Date des images satellite : 10/4/2013 45°18'33.32"N 8°48'56.01"E élév. 212 m altitude 629.39 km

Study area

Pro- and retro-side foreland and external zone non or low-grade metamorphic rocks

- Quaternary
- middle Miocene - Pliocene
- Lower Oligocene - lower Miocene
- Eocene to lower Oligocene
- Mesozoic cover

Basement:

- External Crystalline Massifs
- * Andesitic volcanism

Internal zone low-grade metamorphic rocks

- Ophiolite
- Helminthoid flysch

Internal zone high-pressure low temperature metamorphic rocks

- Internal Crystalline Massifs
- Briançonnais zone

Piedmont Schistes lustrés - Viso complex

- Internal Piedmont complex
- External Piedmont complex

Apulian plate:

- Austro-alpine zone

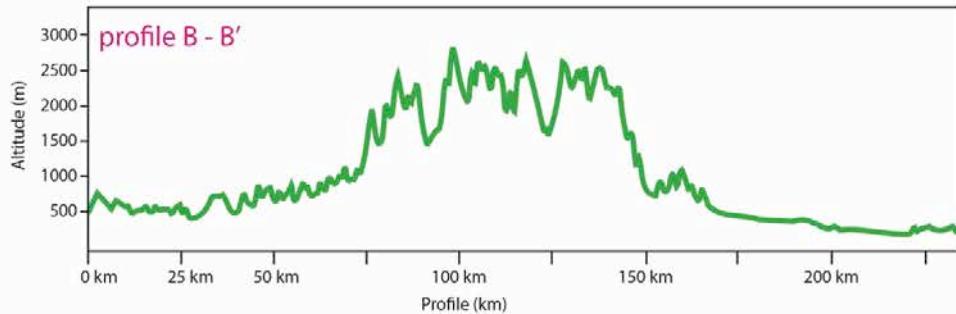

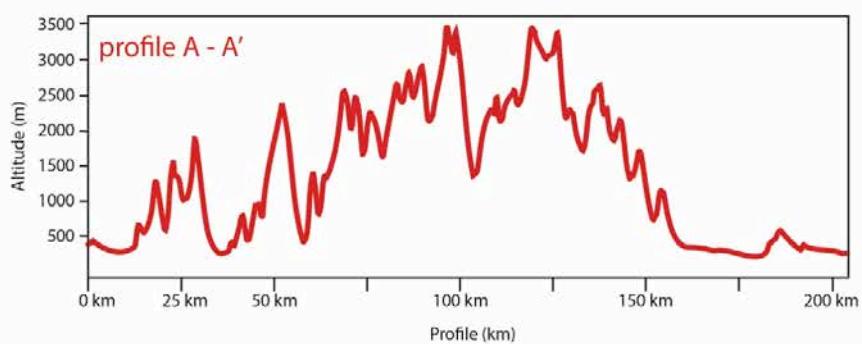

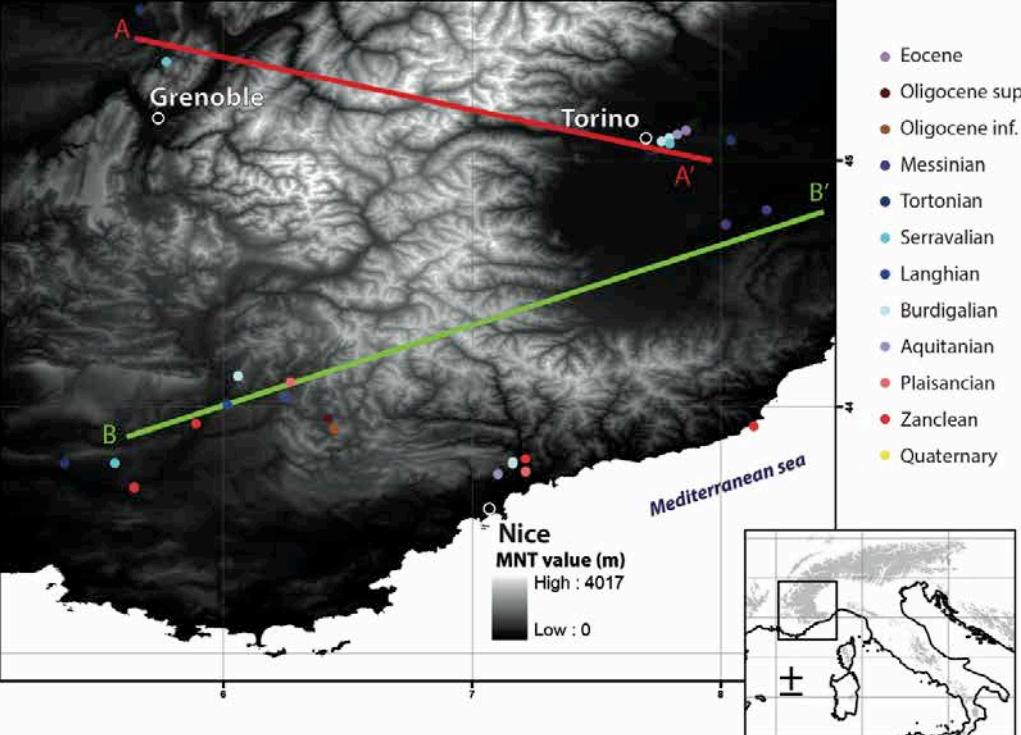

- Focus on the southern Western Alps

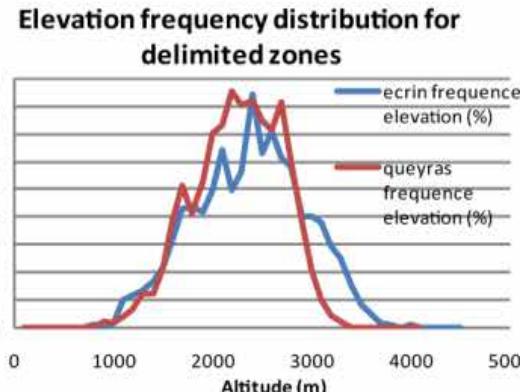

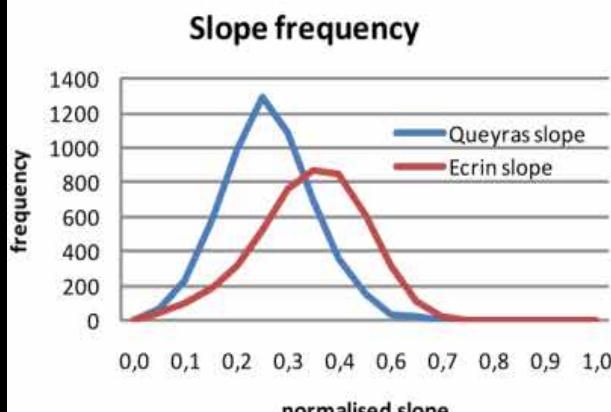

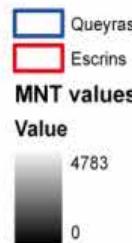

Jourdan, 2012

Les Ecrins incisés et pas le Queyras?

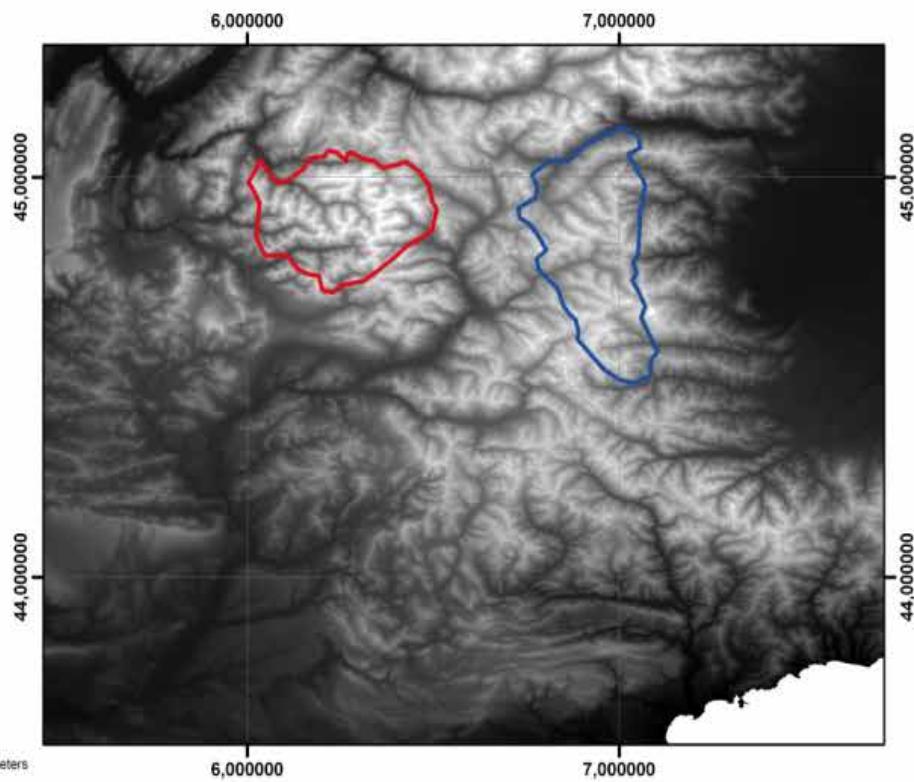

average altitude
maximum altitude
Minimum altitude

	Ecrins	Queyras
average altitude	2324,07	2208,61
maximum altitude	3915	3233
Minimum altitude	747	894

	Queyras slope	Ecrin slope
Average slope	24,262	32,360
standard deviation	8,7978	10,6285

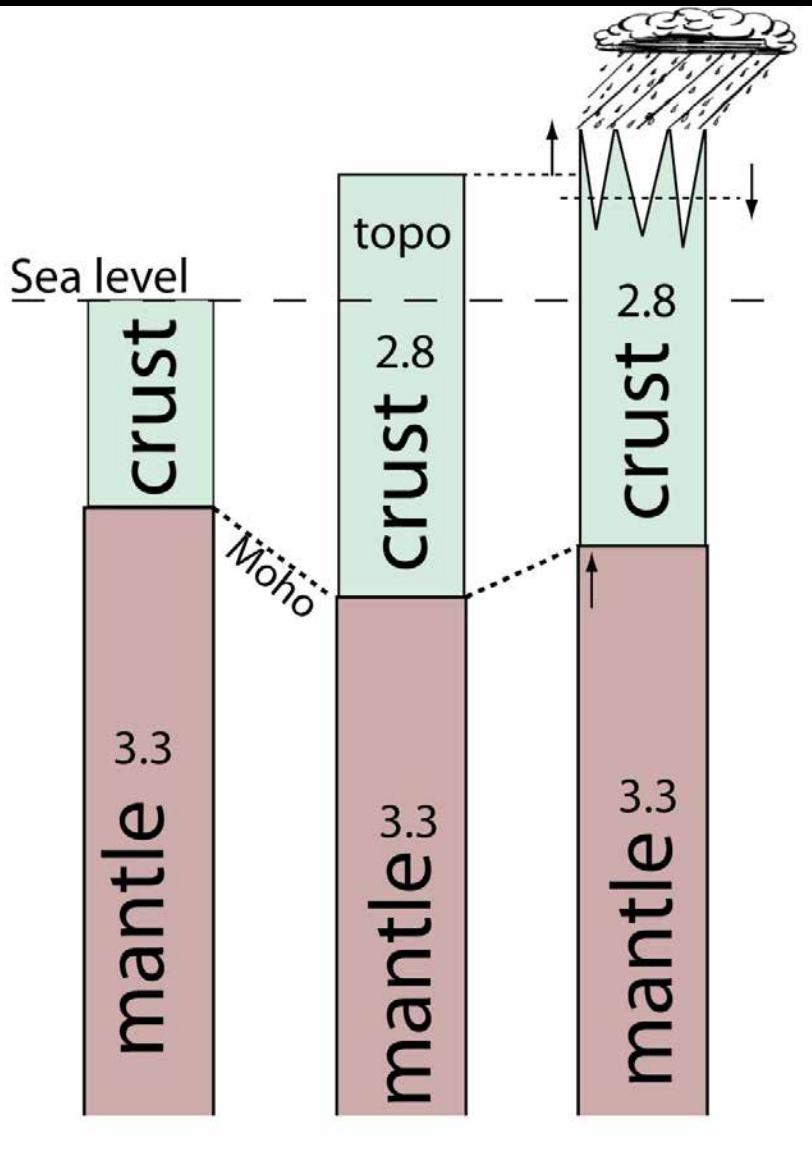

Queyras and Ecrins geomorphological comparaison

Thermochronological record of exhumation : lag time

Importance des changements climatiques:

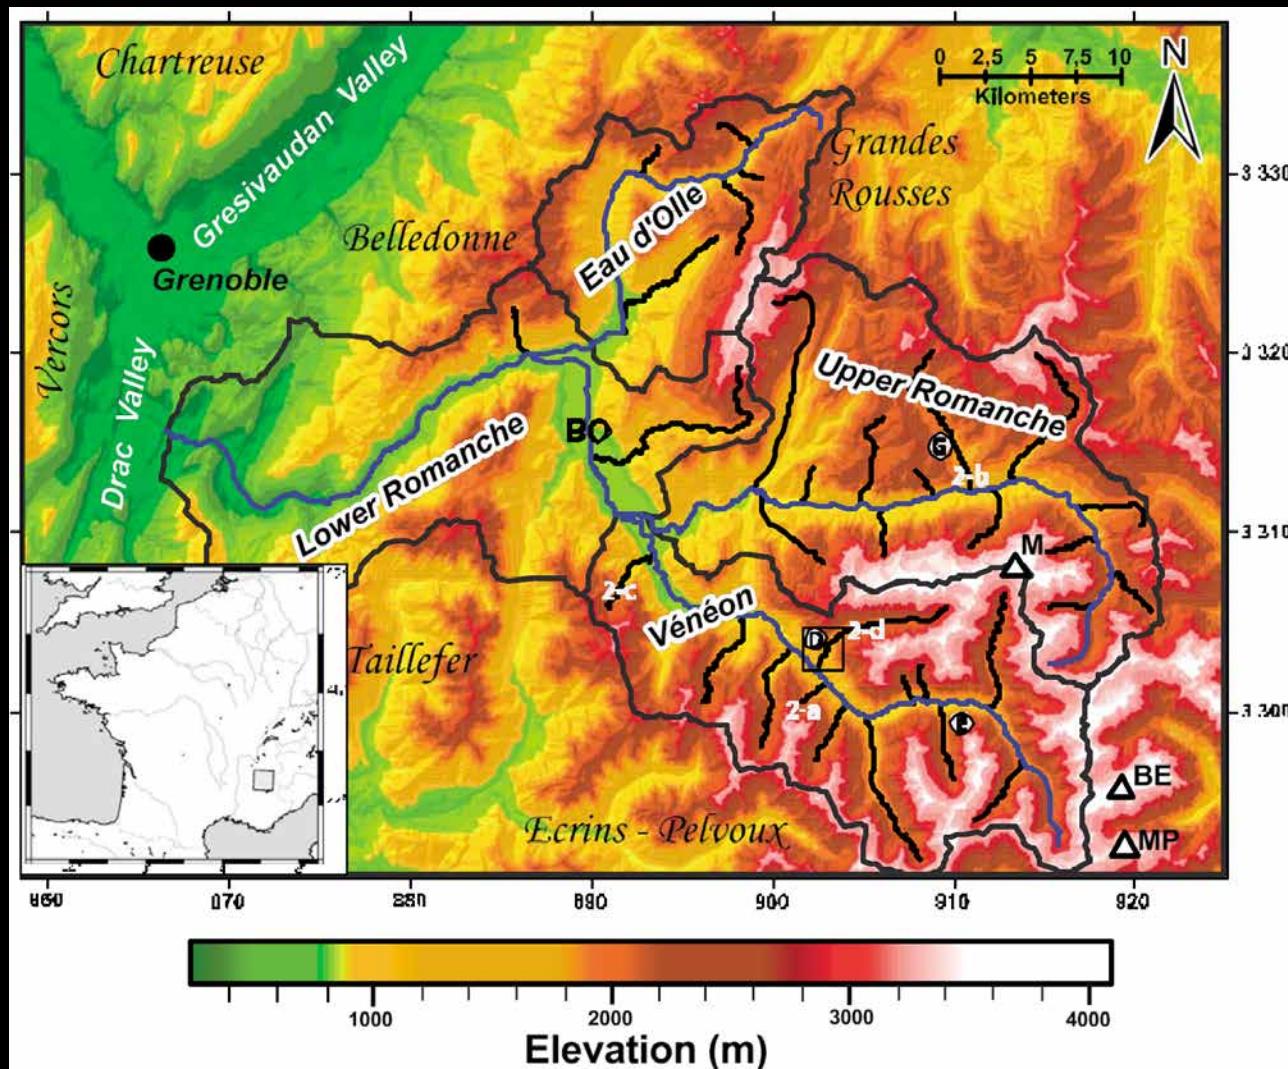

Principe d'équilibre isostatique:

Erosion d'une épaisseur moyenne "h":

- diminution de l'altitude moyenne ($h/6$)
- augmentation potentielle de l'altitude des sommets (dépend de l'erosion des sommets, max= h)

Conséquences potentielles:

- Augmentation de la surface au dessus de l'ELA (creation de glaciers)
- renforcement de la barrière orographique (plus de précipitations en altitude)
- rétroaction positive: augmentation de l'érosion

GLACIER ISÉROIS DE CHAMBERY

Valla et al., 2011

Valla et al., 2011

Climat, érosion et tectonique alpine

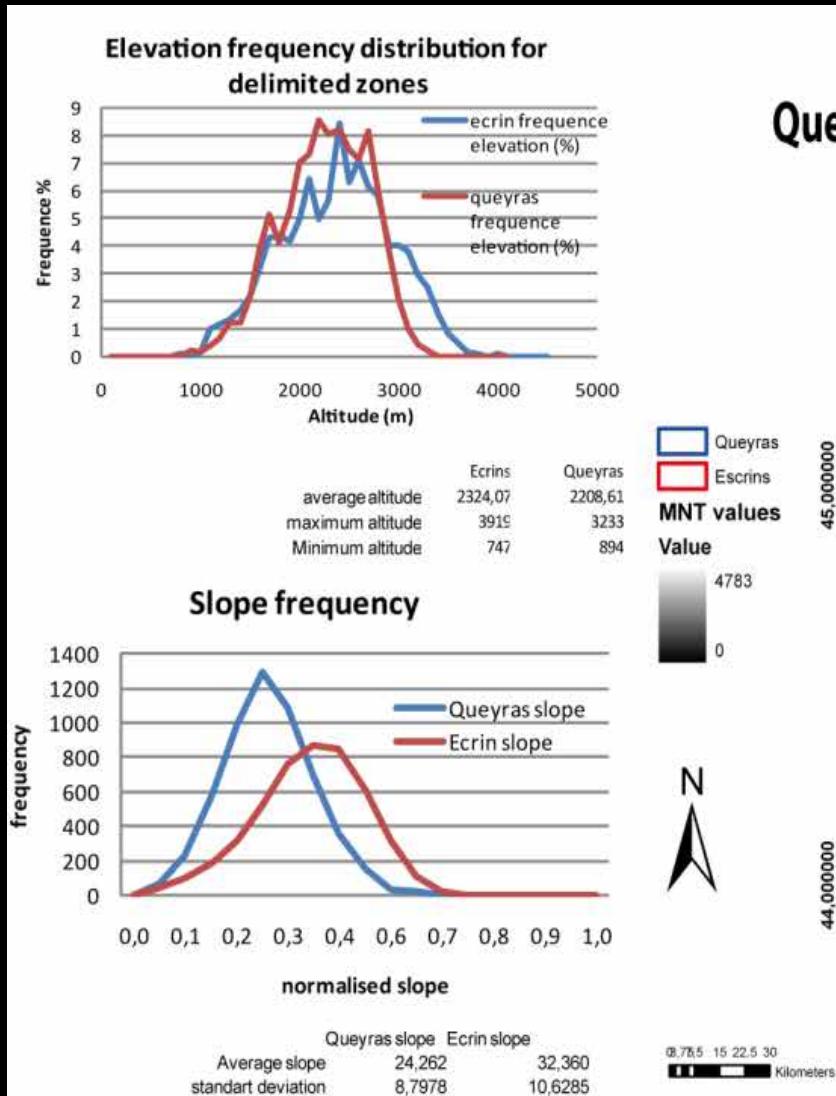

Effets de l'érosion

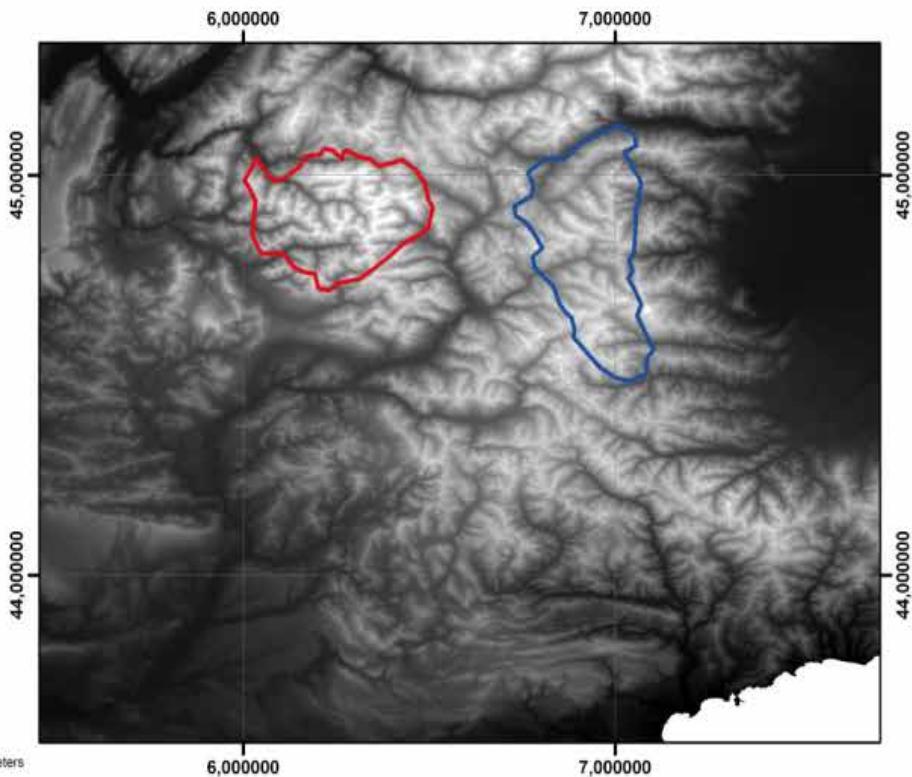

- augmentation du flux sédimentaire, redistribution des masses
- changement de l'état de contraintes
- Surrection induite par la compensation isostatique

Champagnac et al., 2007; Vernan et al., 2013

Pourquoi les écrins incisés et pas le Queyras?

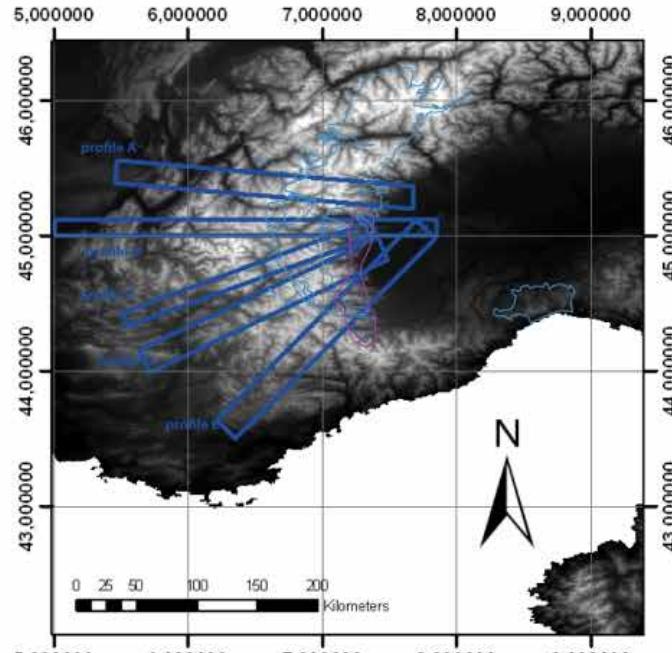

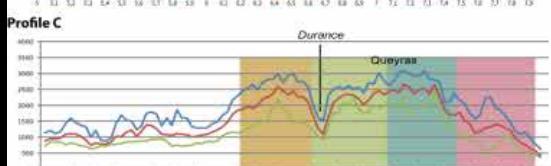

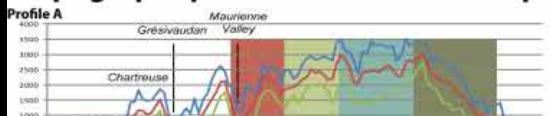

Queyras and Ecrins geomorphological comparaison

Jourdan, 2012

Depuis quand il y a des reliefs dans les Alpes ?

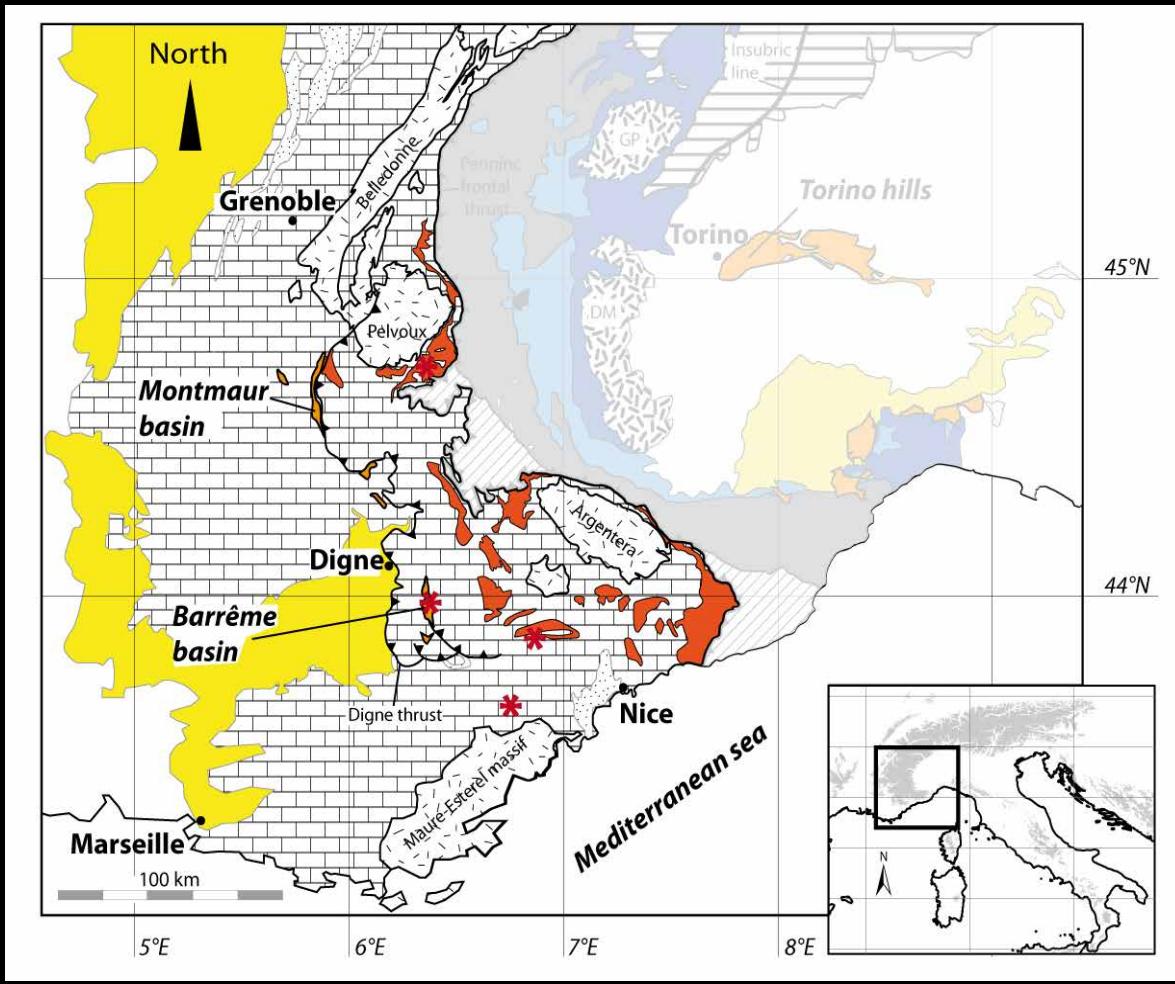

Compilation of tectonic, sedimentologic, paleomagnetic, petrologic data

Alpine geodynamic framework

Main geological units of the Western Alps: External units

External Western Alps units :

- External Crystalline Massifs
- Subalpine chains
- Foreland basin remnants
- Andesitic volcanism (35 – 30 Ma)

Quaternary

middle Miocene - Pliocene

Lower Oligocene - lower Miocene

Eocene to lower Oligocene

Mesozoic cover

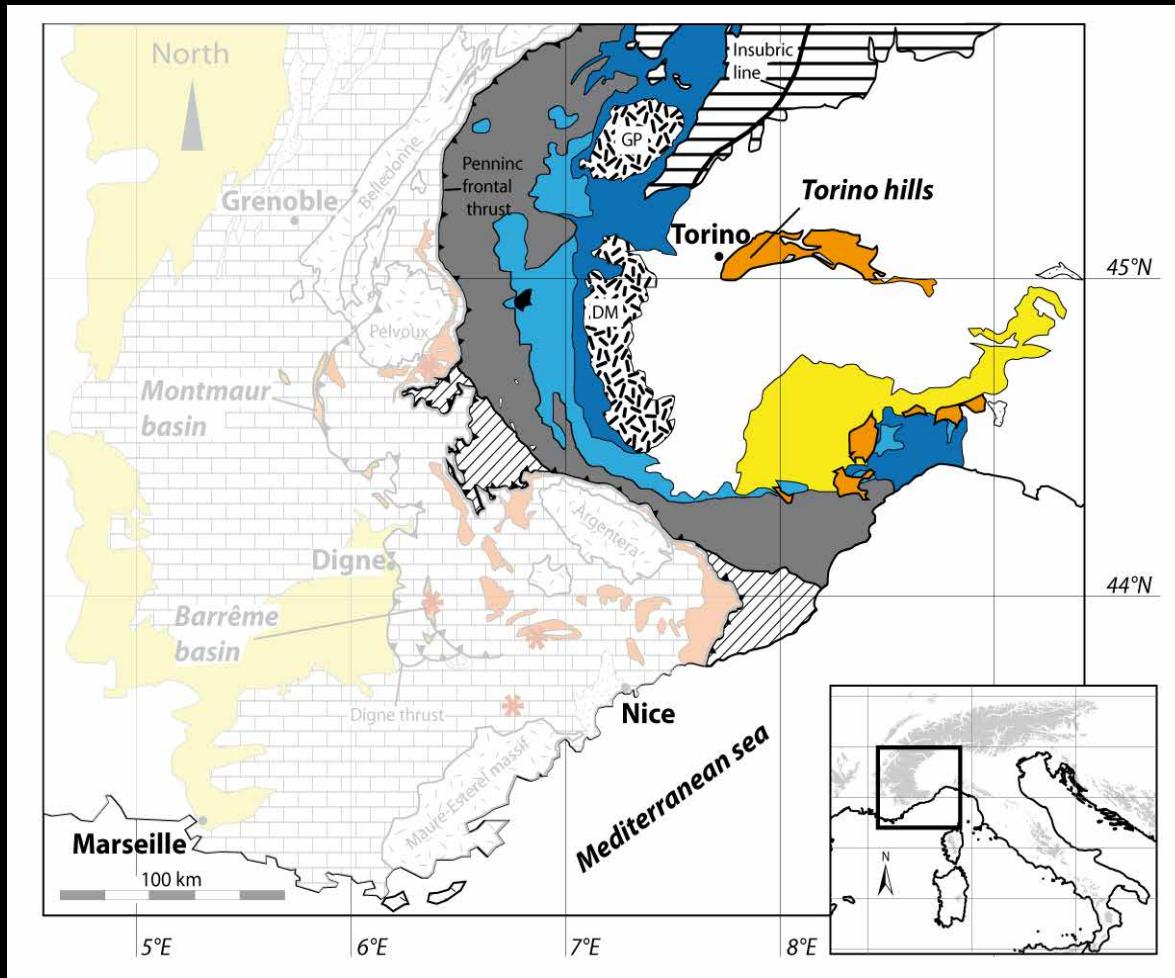

External Crystalline Massifs

* Andesitic volcanism

Saint-Joseph de Rivière conglomérats delta miocène

Main geological units of the Western Alps: Internal units

Internal Western Alps units:

Non-metamorphic:

- Helminthoid flysch
- Obducted Ophiolite

Metamorphic:

- Briançonnais zone
- Piedmont zone
- Internal Crystalline Massifs

Ophiolite

Helminthoid flysch

Internal Crystalline Massifs

Briançonnais zone

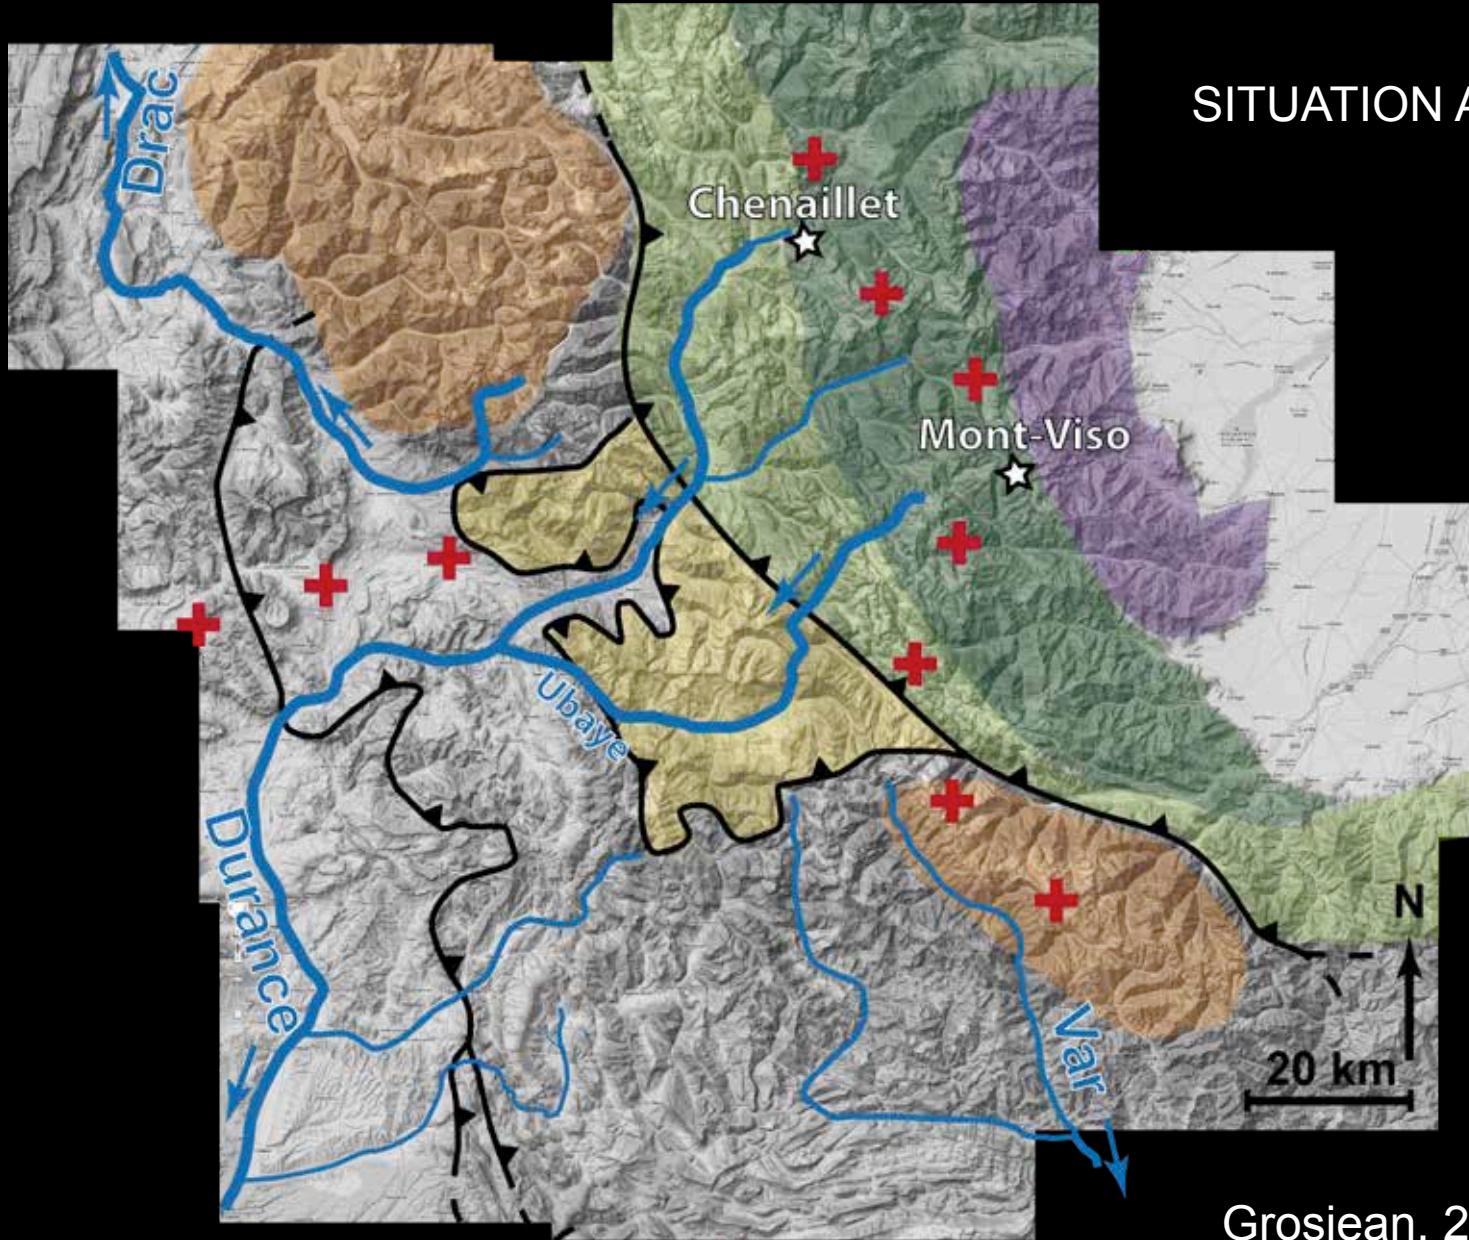

Internal Piedmont complex

External Piedmont complex

Austro-alpine zone

marine

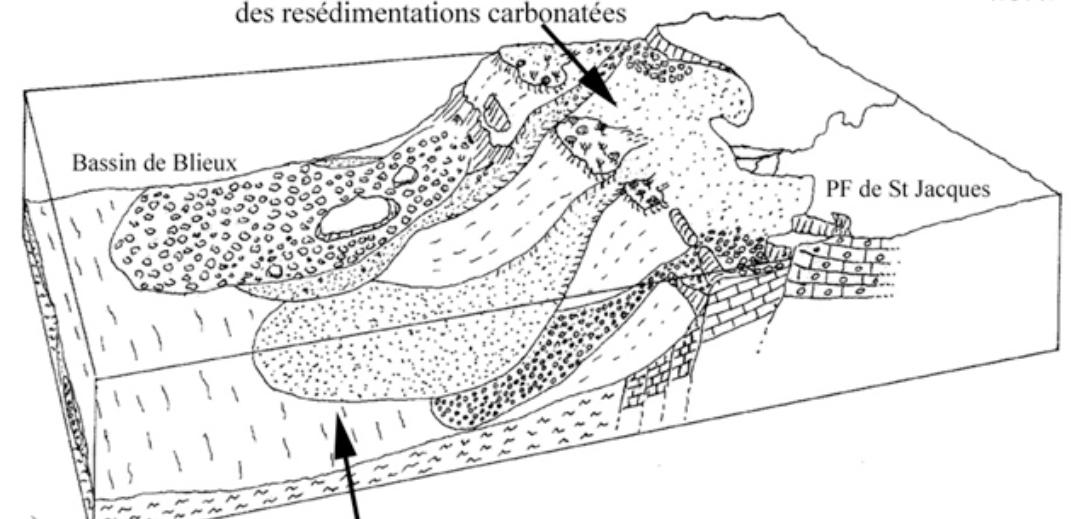

Nummulitic trilogy

Jourdan et al., 2012

ESE

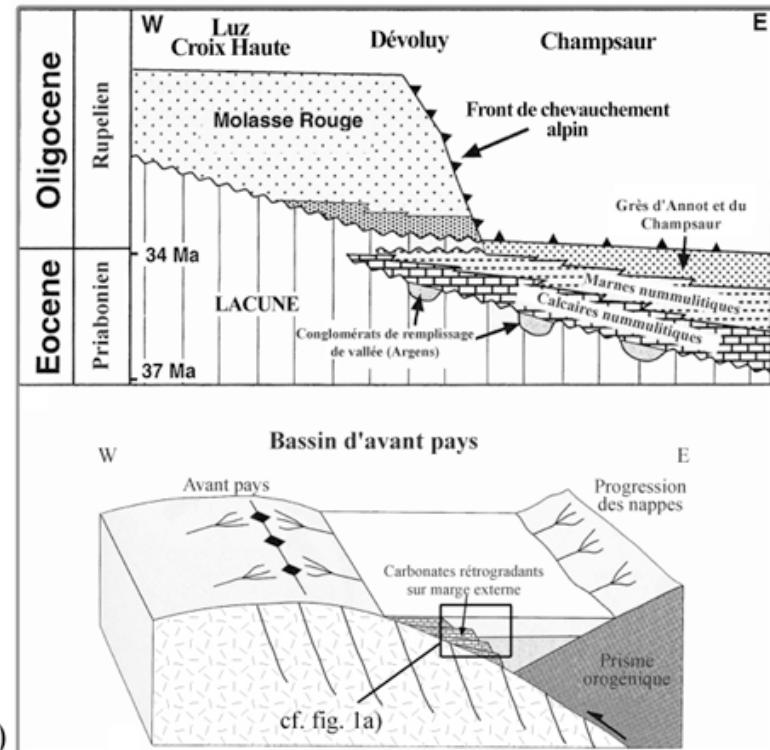

Aires de sédimentations littorales sources
des resédimentations carbonatées

WNW

a)

Sédimentation silto-argileuse du bassin circalittoral dans lesquelles s'intercalent les resédimentations carbonatées

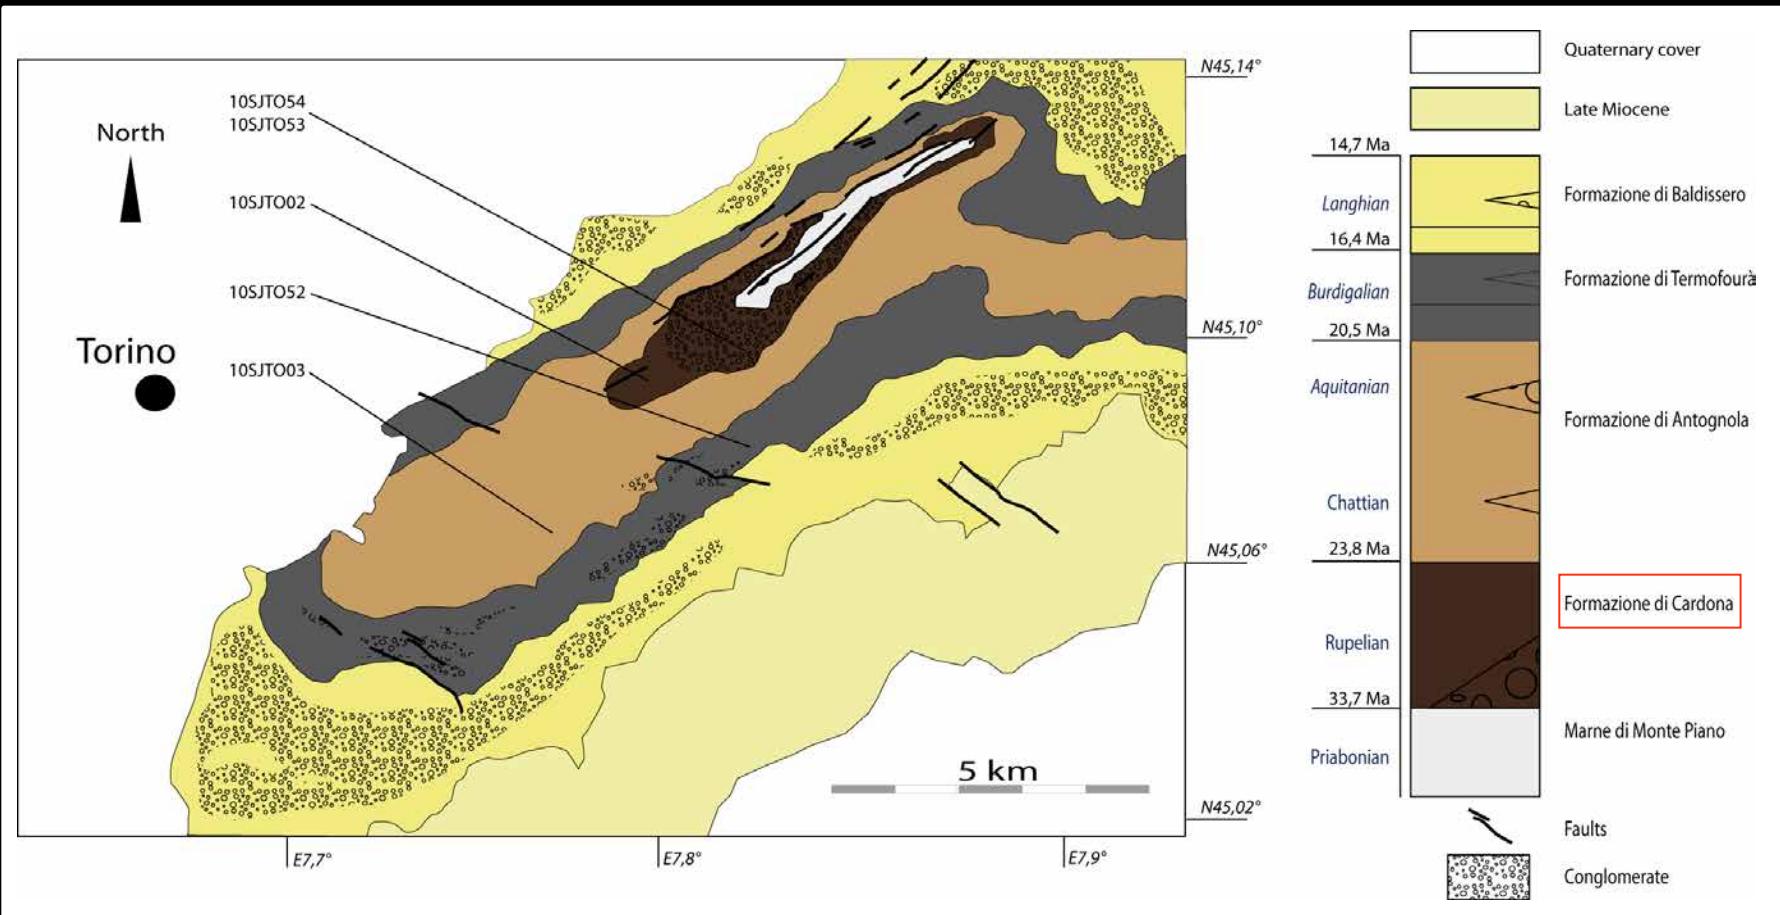

b)

- a) Esquisse paleogéographique représentant les resédimentations carbonatées («Calcaires Nummulitiques») se mettant en place en bas de pente dans la partie sud-occidentale littorale du bassin sub-alpin Priabonien et correspondant à la région de Blieux (d'après Floquet & Léonide, 2005) ;
b) Diagramme litho-chronostratigraphique du bassin d'avant-pays alpin à l'Eocène-Oligocène (adapté, à partir de Gupta, 1997).

Sinclair, 1994

Torino hills

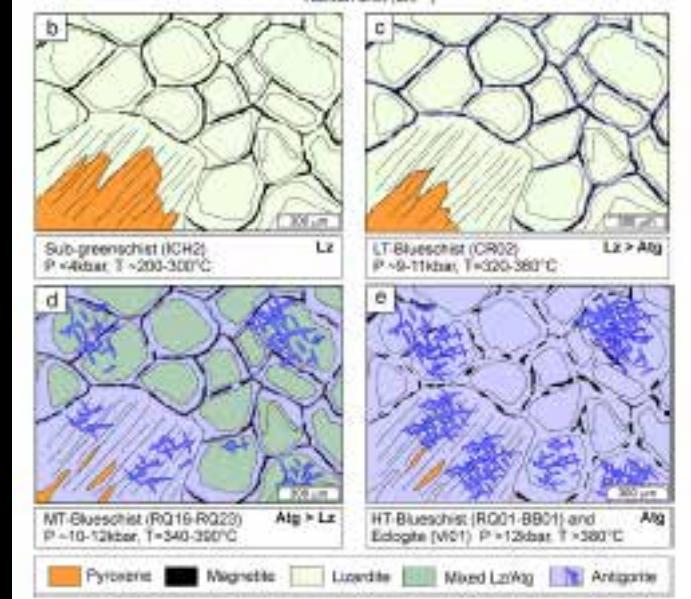

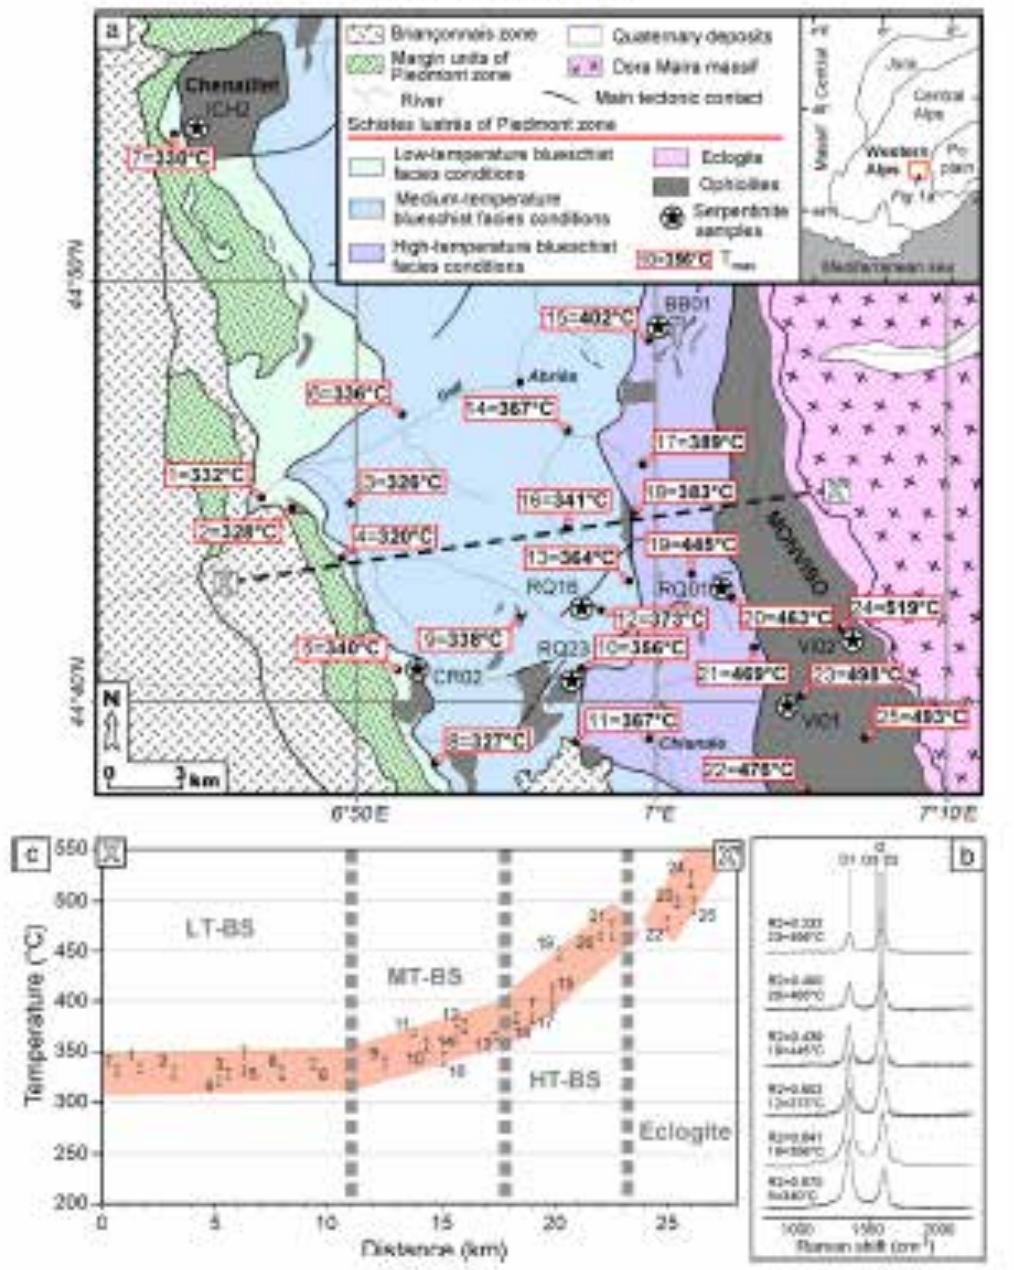

- Torino hills sedimentary record from the Eocene to the Quaternary
- The Cardona Formation (Rupelian) begins to record erosion of the Western Alps

Jourdan et al., 2012

Discriminating the nature of the serpentinites in the Internal Alps

Schwartz et al., 2013

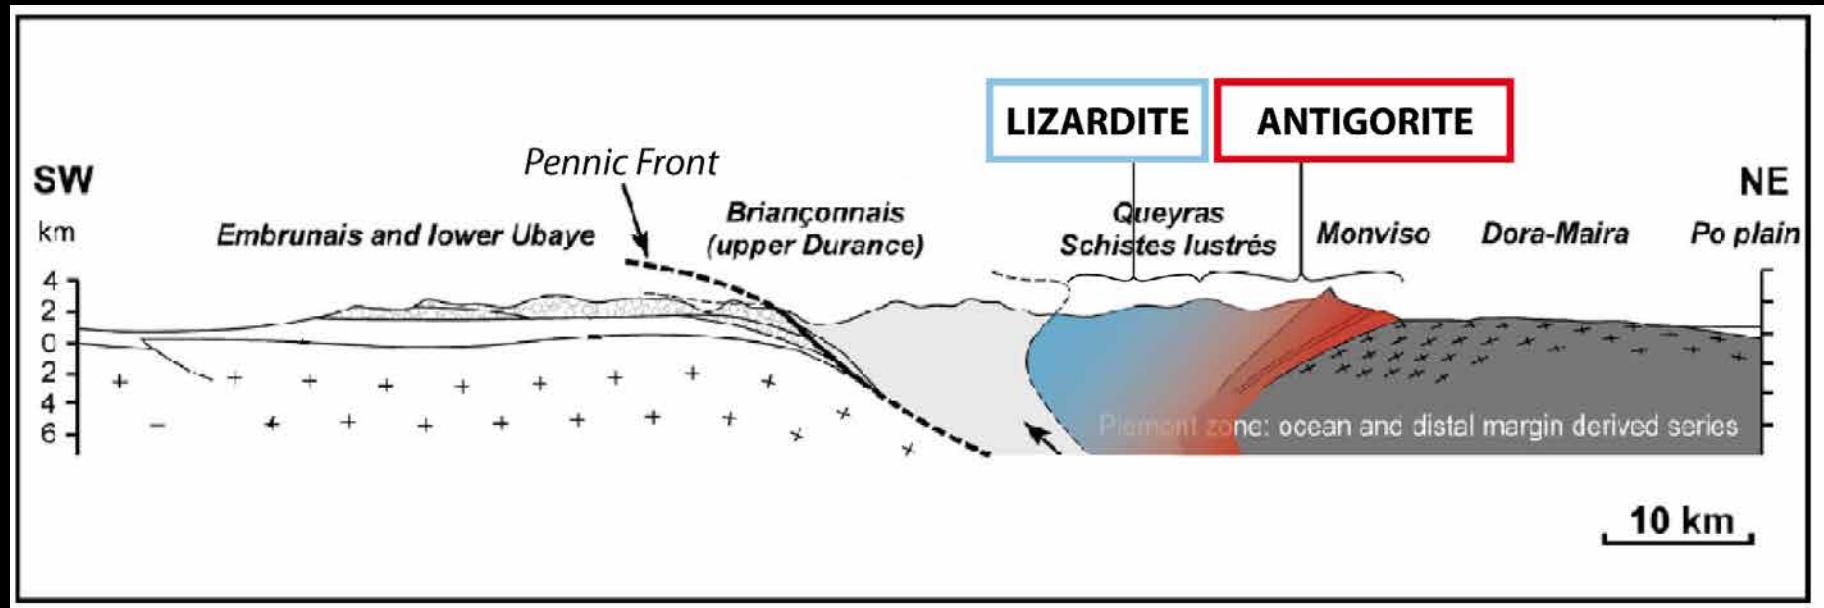

Pebble origin in the Oligocene-Miocene sediments : Serpentinites, Radiolarites, Basalts

Cordey et al. 2012

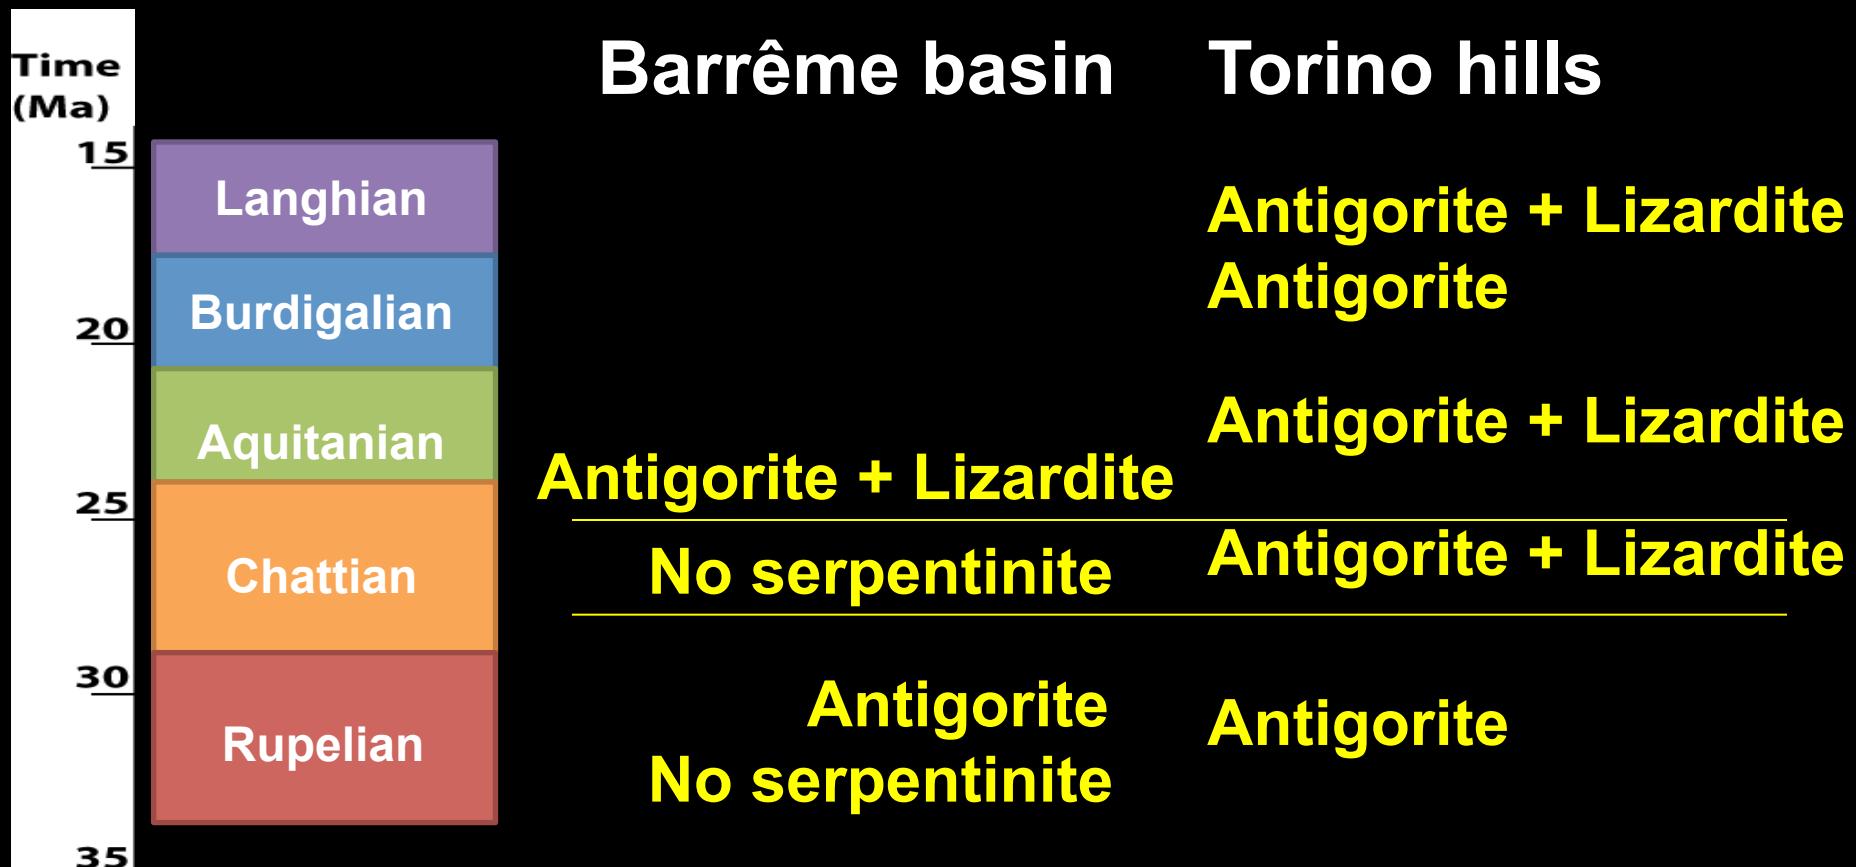

Serpentinite types in the Internal Western Alps

Schwartz et al. 2012, 2013

- Antigorite occurs in the eastern part and antigorite + lizardite in the western part of the Internal Western Alps

Serpentinite evolution through stratigraphic record

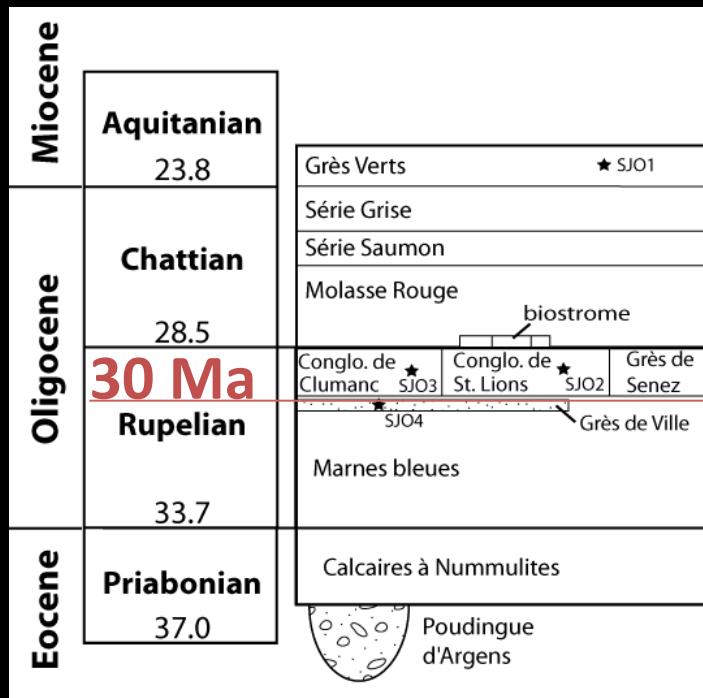

- Antigorite = high-grade metamorphic serpentinite
- Lizarditite = low-grade metamorphic serpentinite

Oligocene pro-side foreland basin

« Matériel exotique » = ophiolites/blueschists
Termier 1895 in Chauveau and Lemoine 1961

Barrême basin

Source areas

Internal Western Alps

Paleocurrent: NE – SW

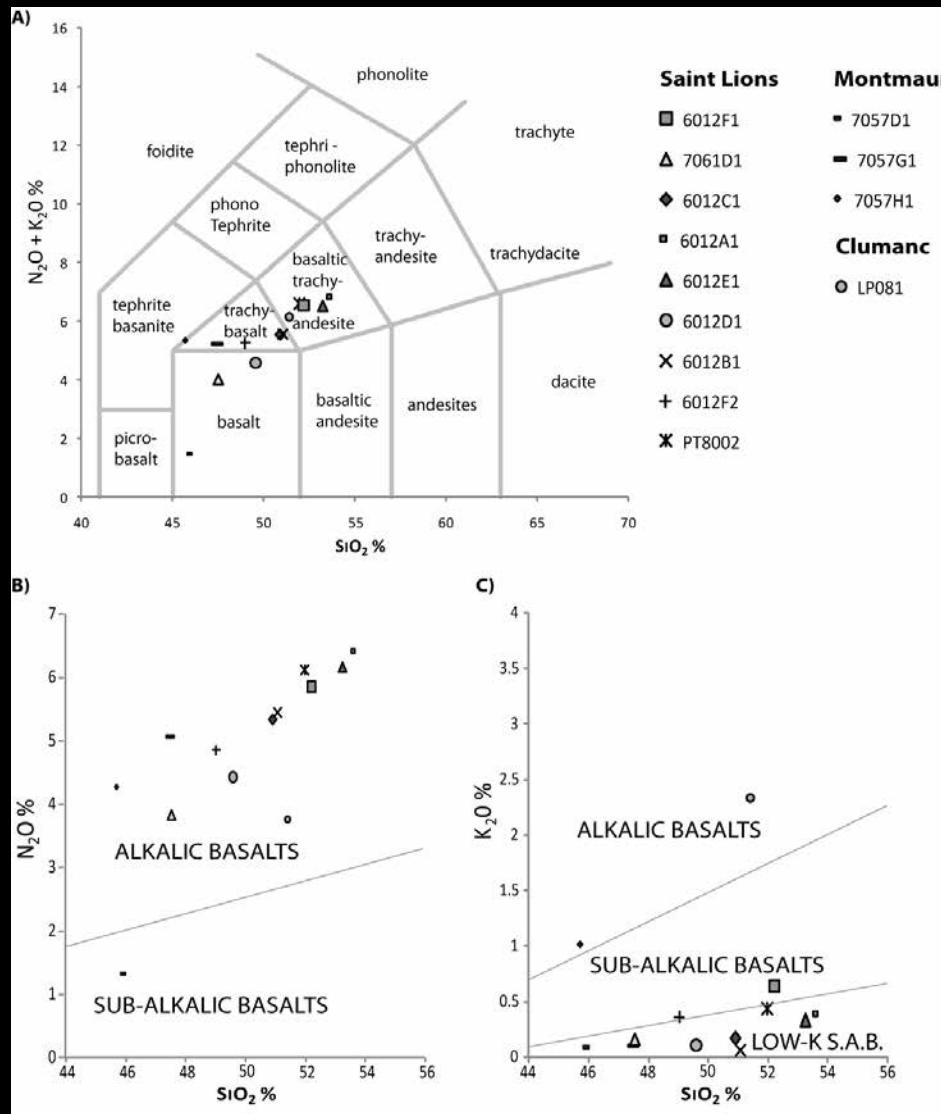

Paleocurrent: S – N

Joseph and Lomas 2004

Corsica, Maures-Estérel massif

- At 30 Ma deposition of pebbles from the Internal Alps
- Significant change in paleocurrent directions

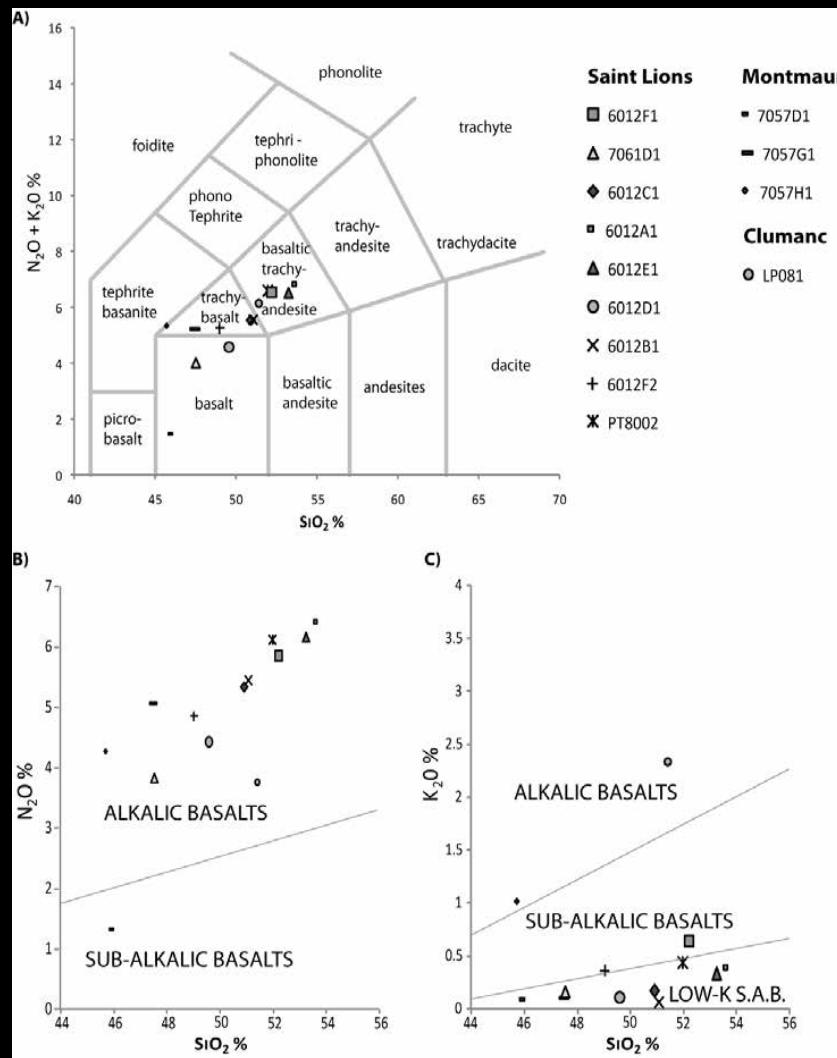

Geochemical analyses

- Major and trace element analyses for basalt pebble characterization for provenance analysis

Jourdan et al., 2012

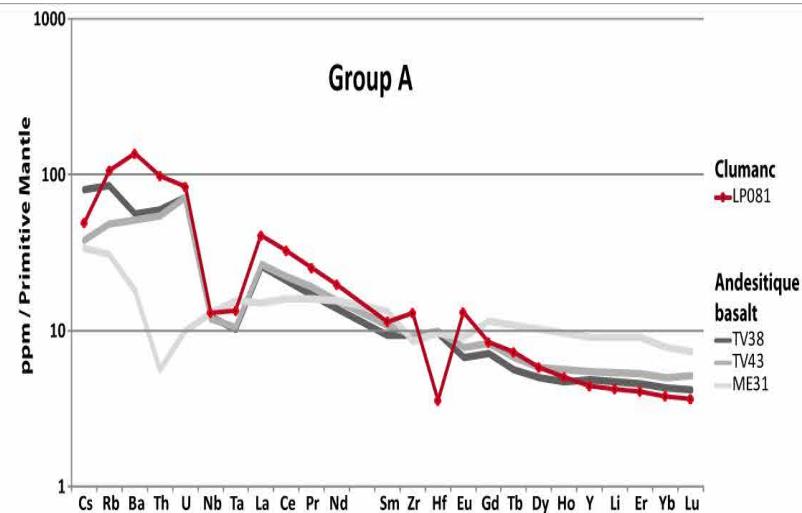

Geochemistry of basalt pebbles in the foreland basin

- Before such pebbles were described only as andesites
- Major element analyses show that non-metamorphic basalts from the 30 Ma Barrême basin and Montmaur conglomerates are:
 - Basaltic trachy-andesitic
 - Trachy basalt
 - Basalt

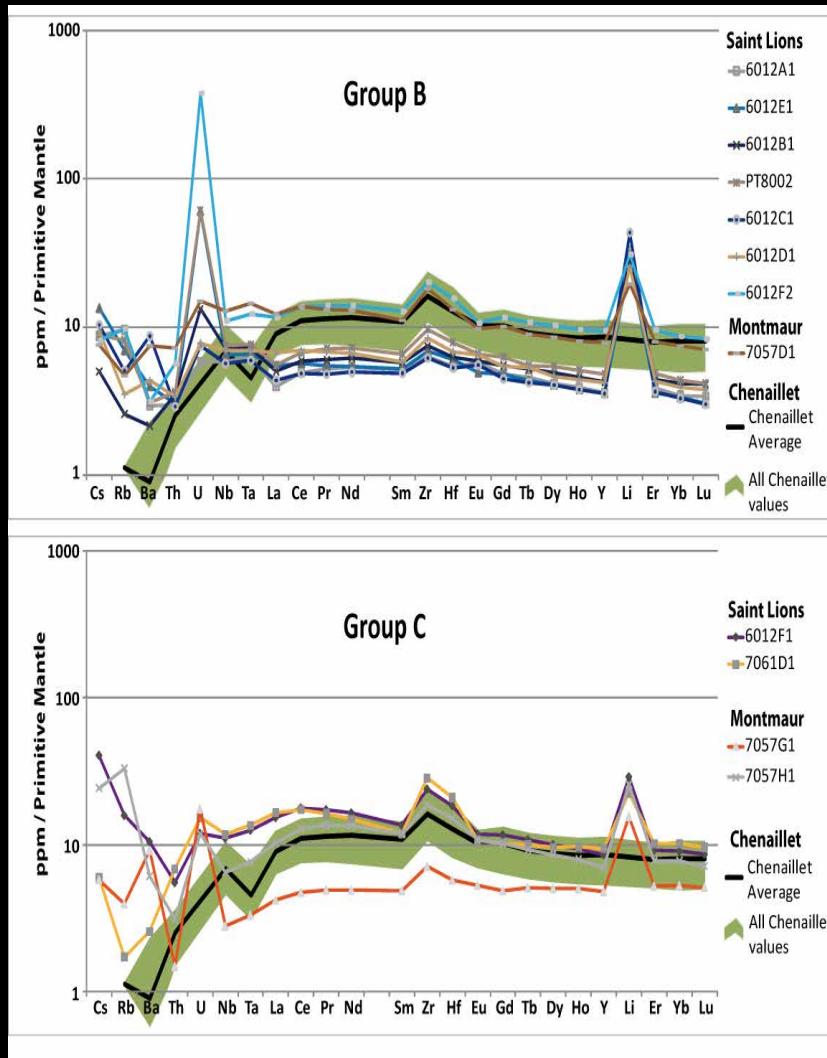

and fall mainly into the alkalic basalt or low-K sub-alkalic basalt fields

Geochemistry of basalt pebbles in the foreland basin

- The basalt pebble A from the Clumanc conglomerate is similar to andesitic basalt from the Taveyannaz and Champsaur units (*Boyet et al. 2001*)

Geochemistry of basalt pebbles in the foreland basin

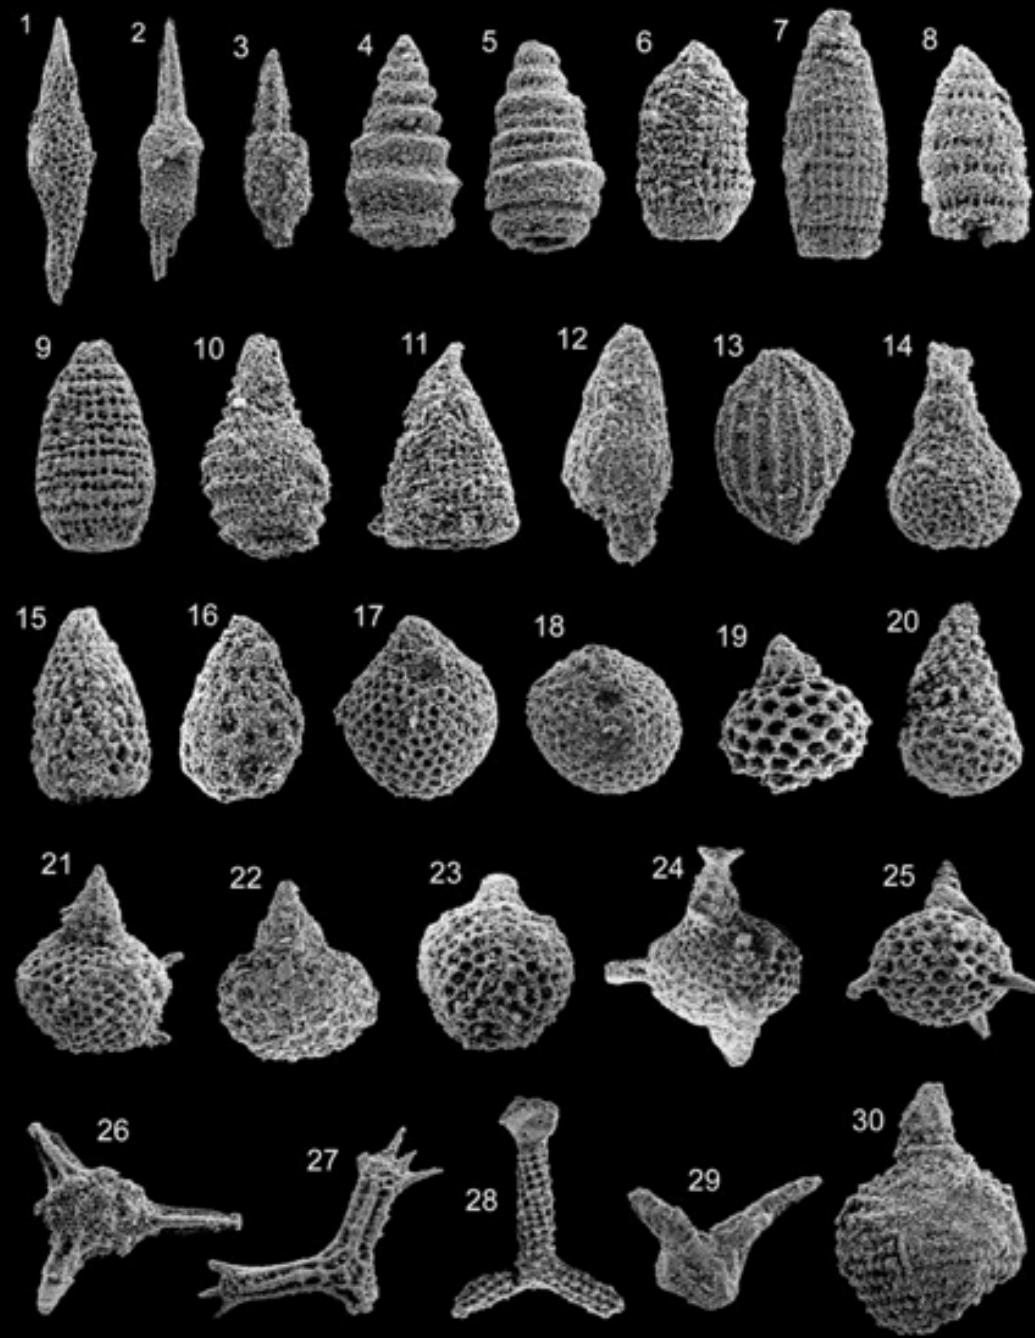

- Group B and C have patterns somewhat similar to basalt from the obducted Chenaillet ophiolite unit
- Positive anomalies are caused by hydrothermal alteration in the source and/or weathering in the sedimentary system

Pebble origin in the Oligocene-Miocene sediments : Serpentinites, Radiolarites, Basalts

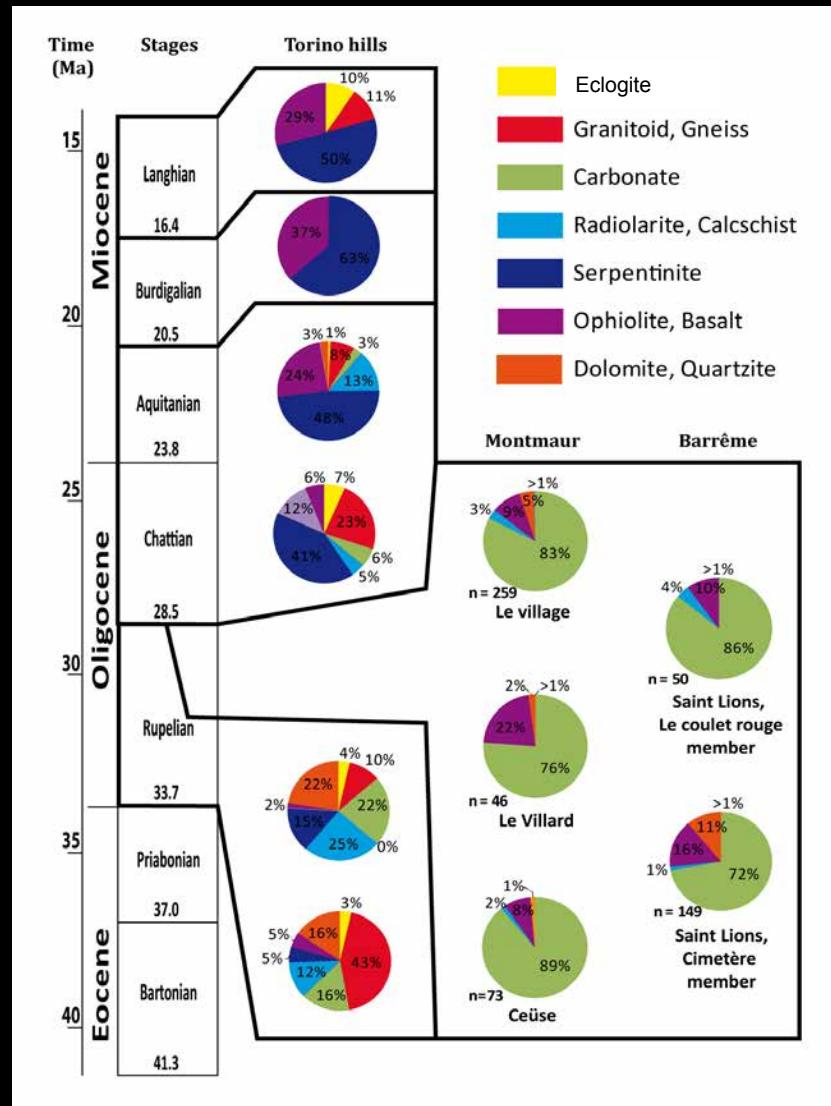

Cordey et al. 2012

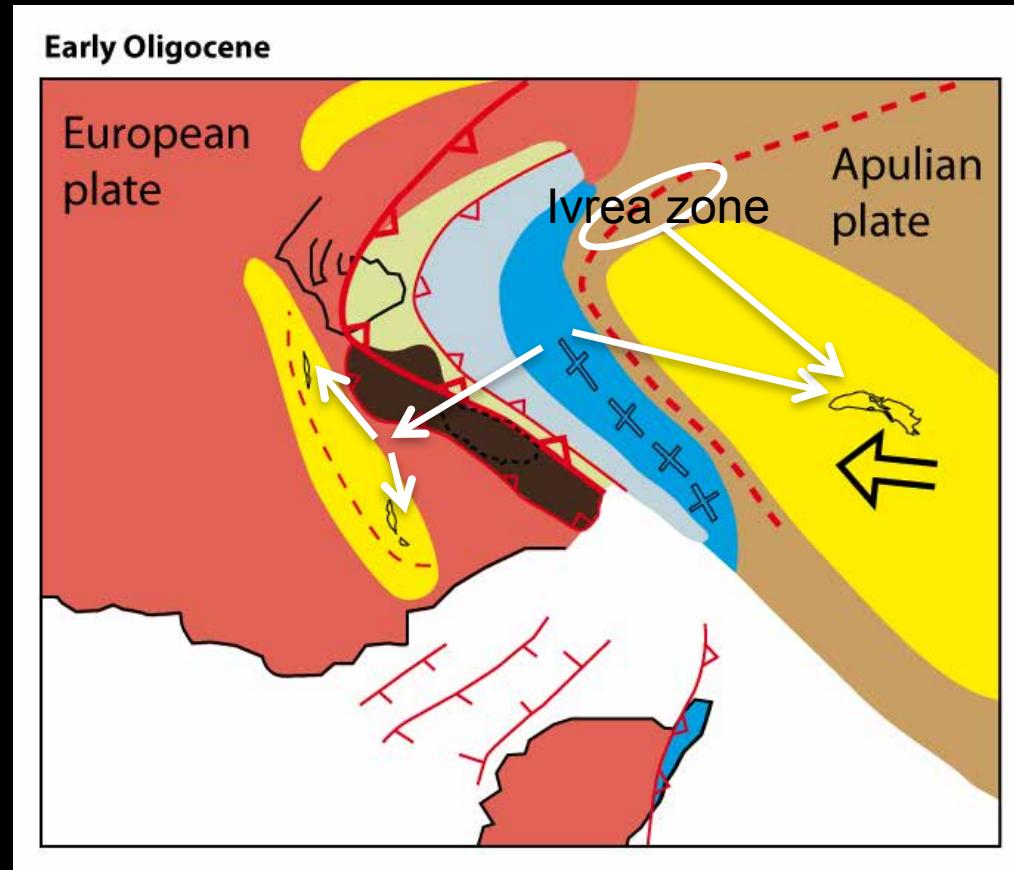

Cordey et al.
Swiss Geol J, 2012

Pebble population evolution

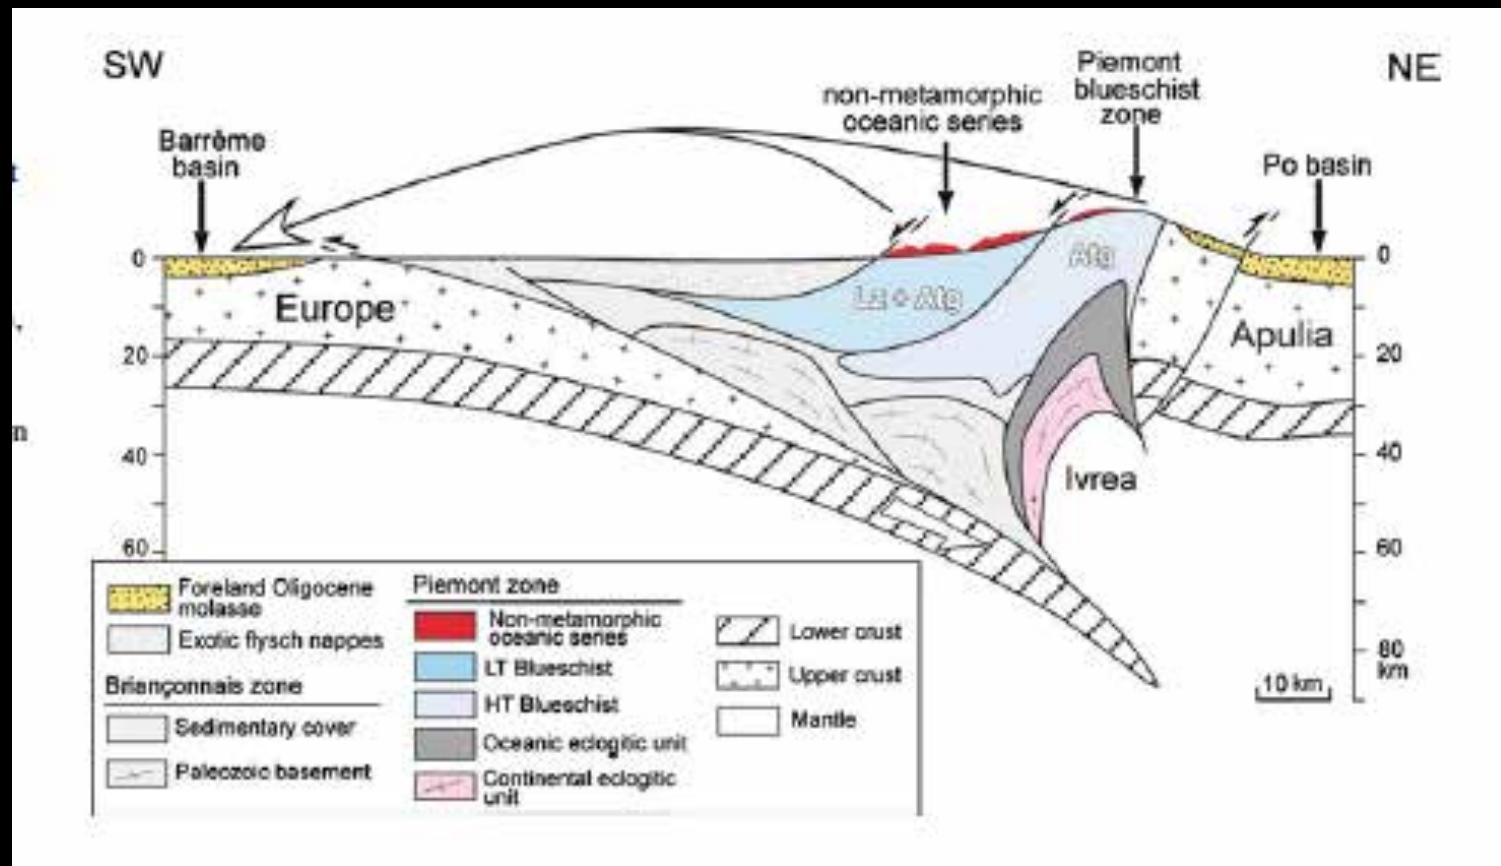

- Proportion of serpentinite pebbles strongly increases from the Late Oligocene in the Torino hills
- The presence of basalt pebbles in all Oligocene foreland basin remnants hints at a wide distribution of obducted ophiolites in the Western Alps at that time

Sediment provenance

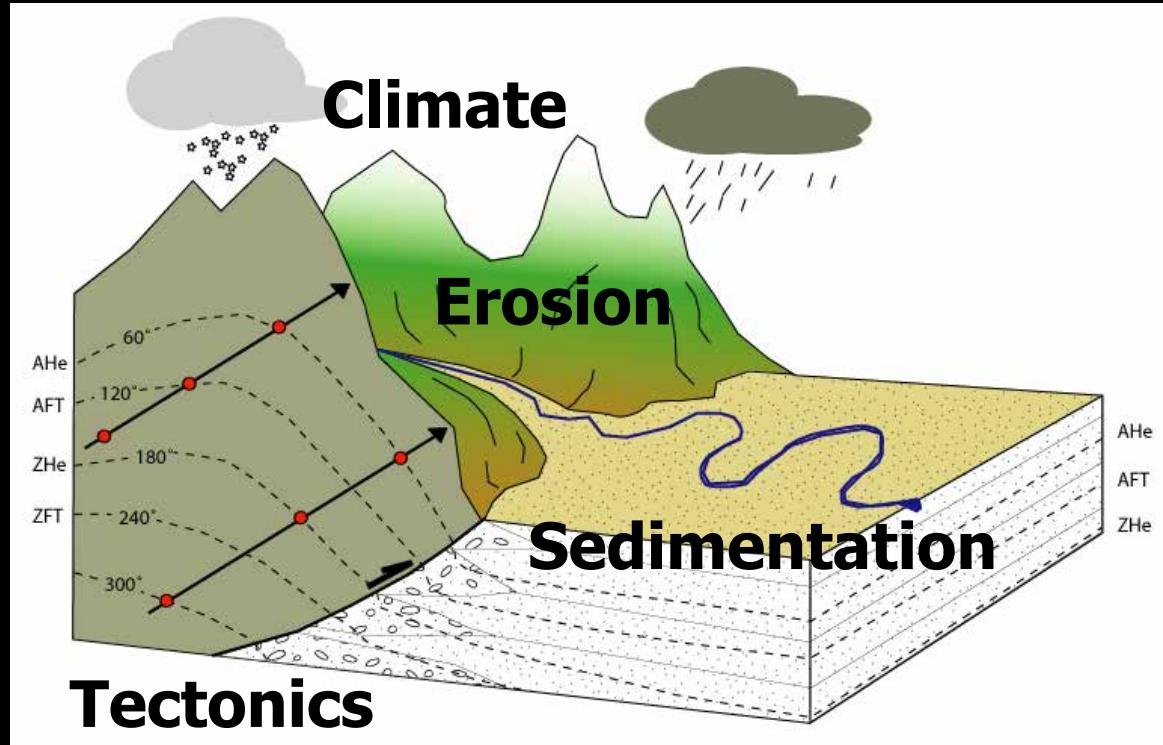

Jourdan et al., 2012

Torino hills: Granodiorite pebbles derived from the Ivrea zone and serpentinite pebbles from the Piedmont zone
Barrême basin: Basalt pebbles from Chenaillet or similar ophiolites. Zircons from the Internal Alps

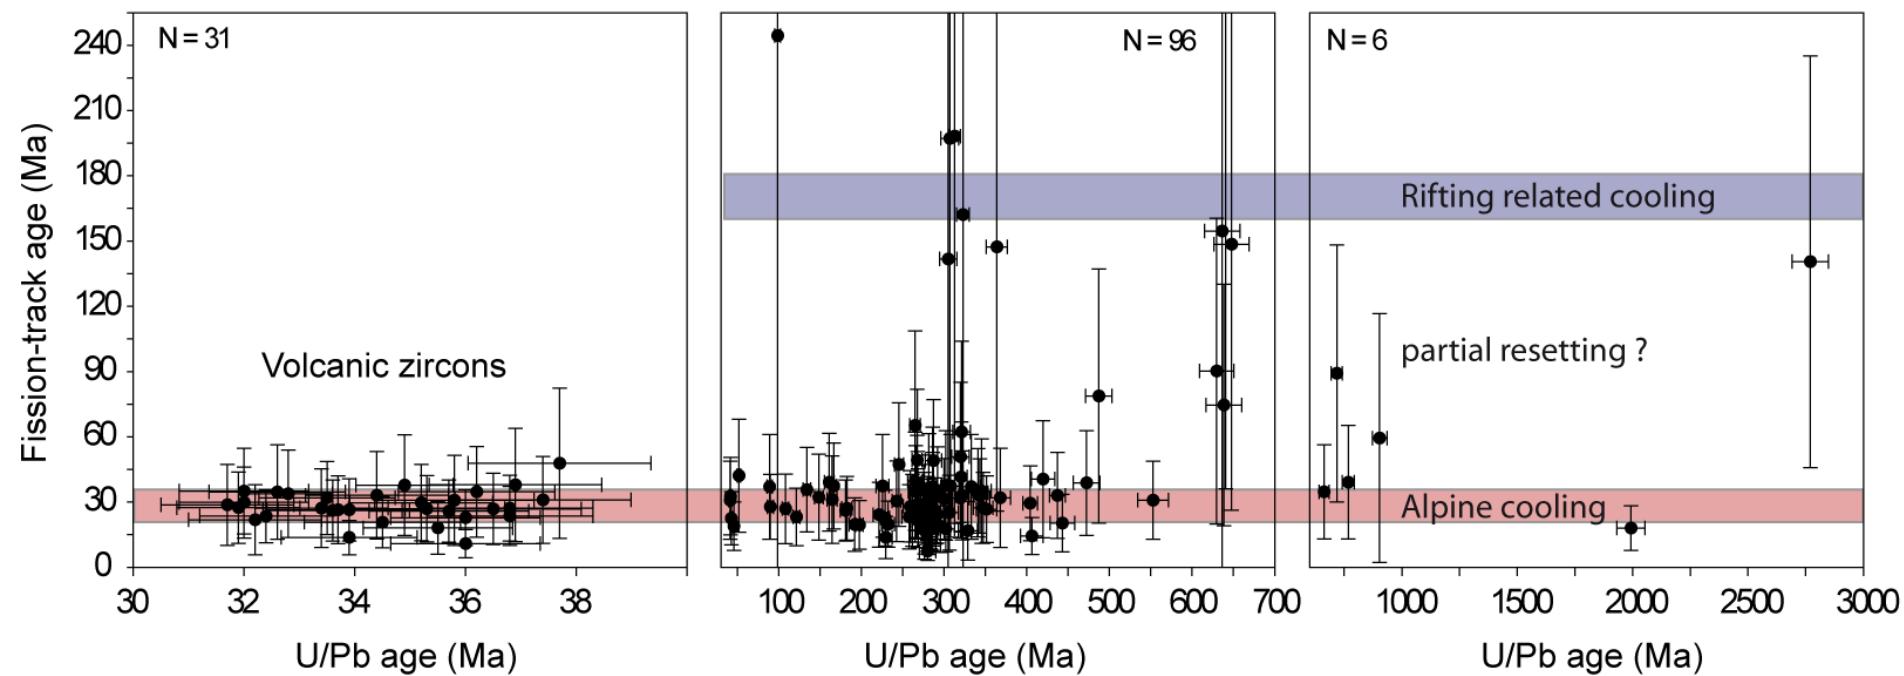

Thermochronological record of exhumation : lag time

Bernet 2009

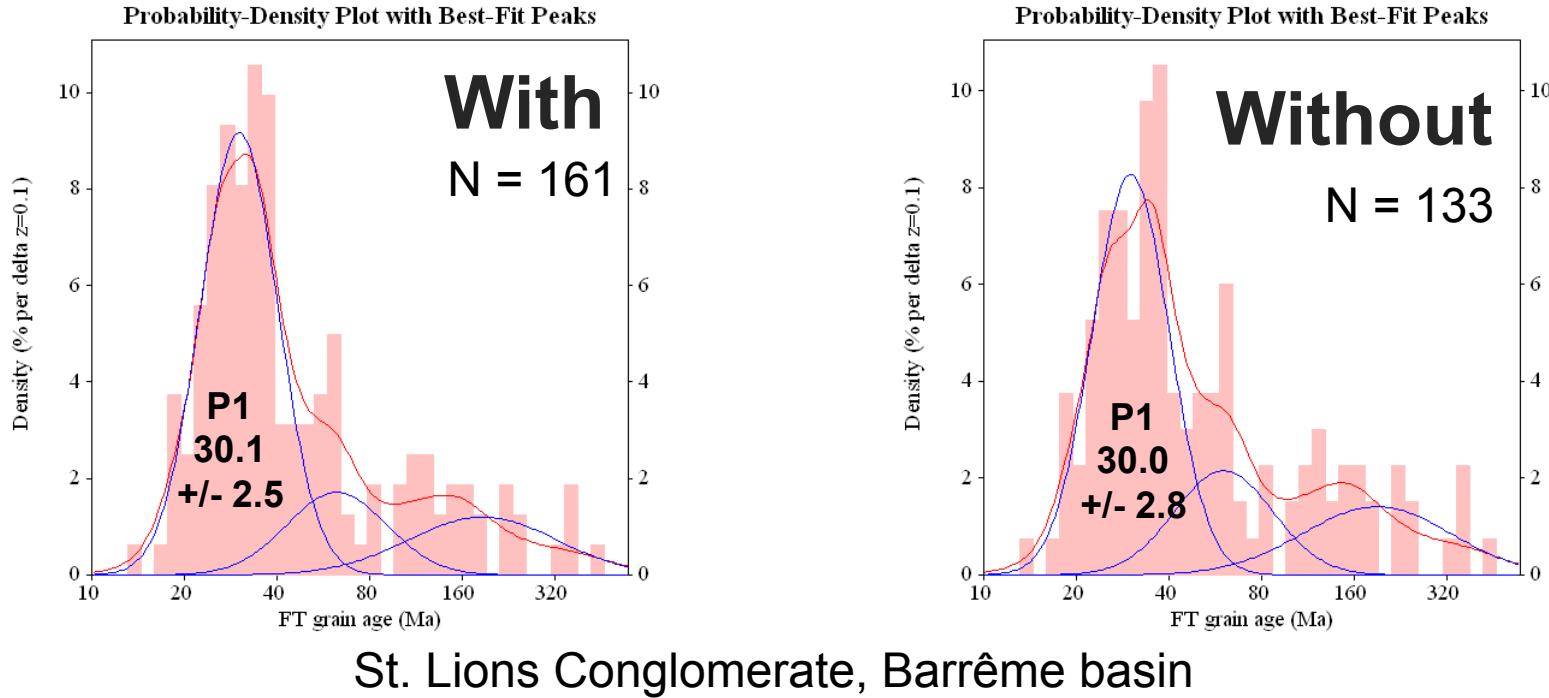

- With depth temperature increase depending thermal gradient
- Exhumational cooling of rocks
- The time of cooling below the closure temperature is recorded in apatites and zircons

ZFT and U-Pb double dating results in the pro-side foreland basin

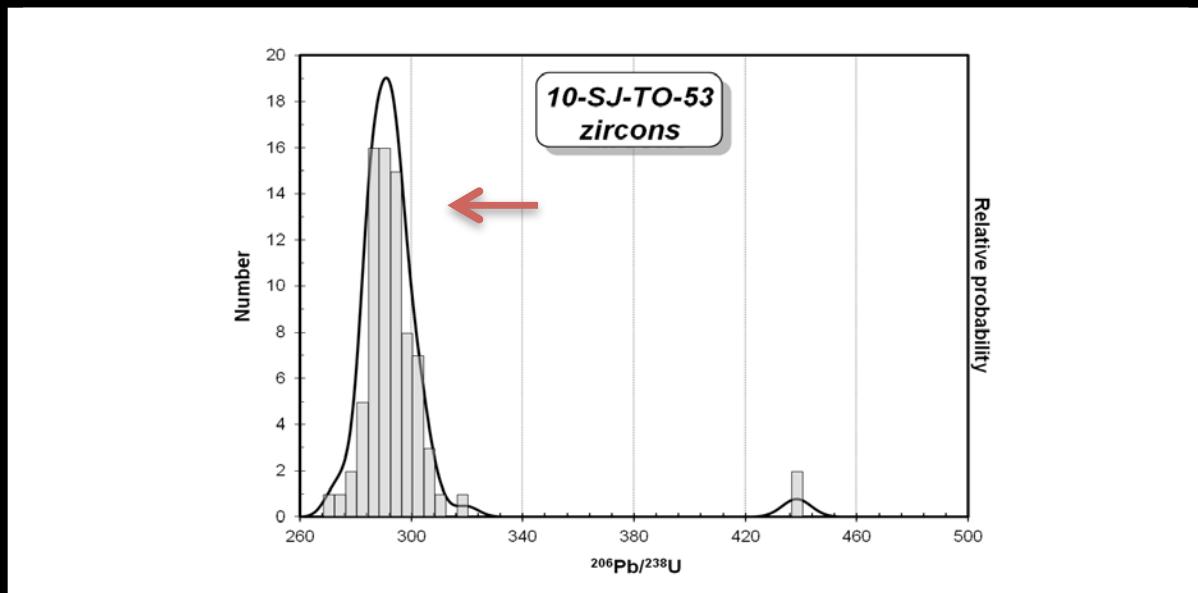

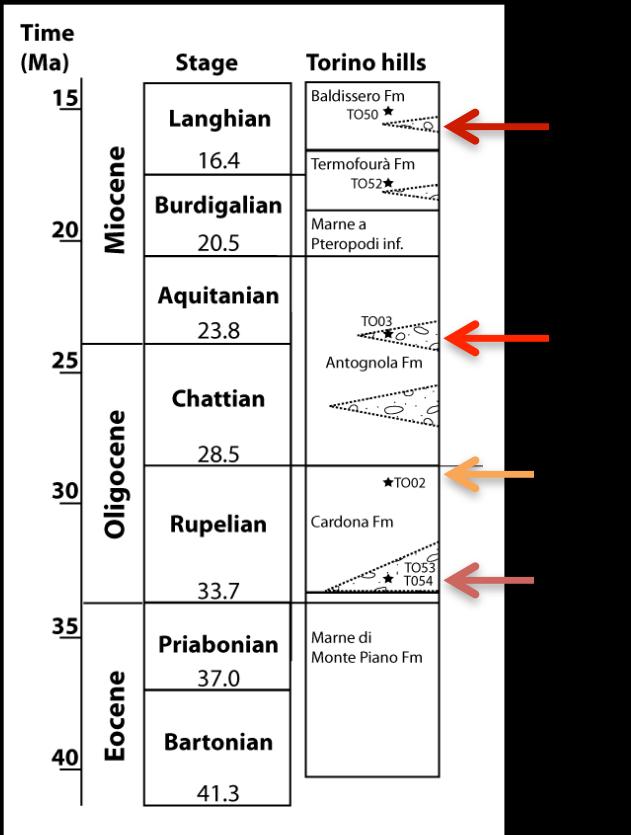

- A strong Alpine cooling signal in spite of the presence of Oligocene volcanic zircons

ZFT and U-Pb double dating results in the pro-side foreland basin

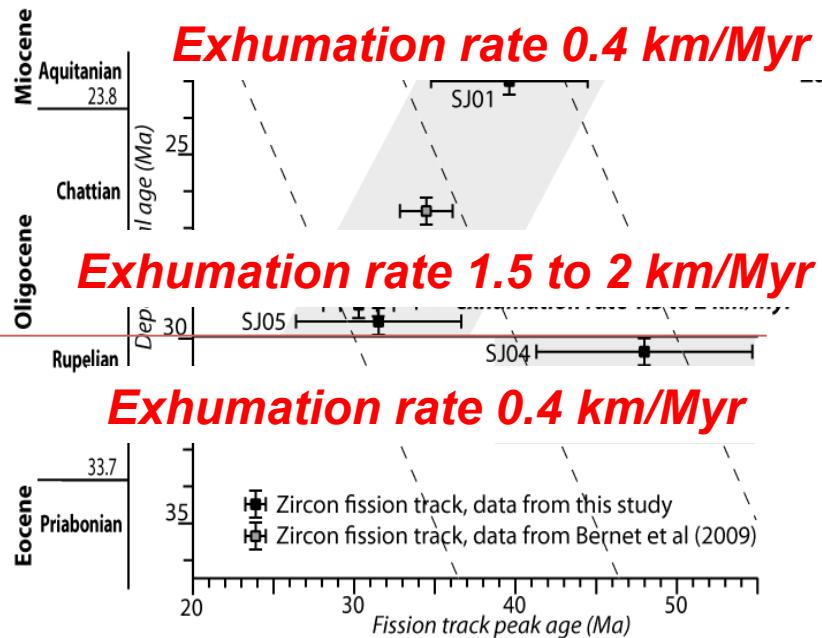

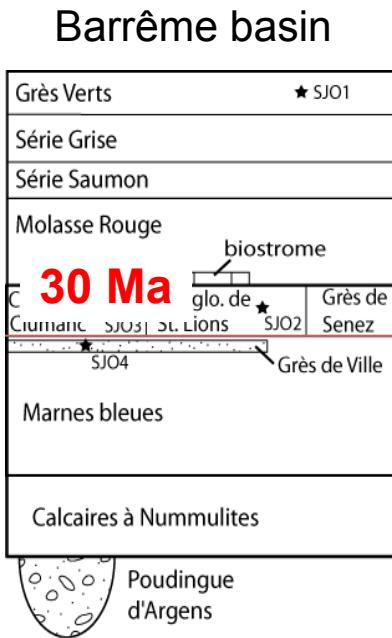

- Removal of volcanic zircons from the dataset to obtain a pure exhumation signal

ZFT-U/Pb double dating results Torino hills

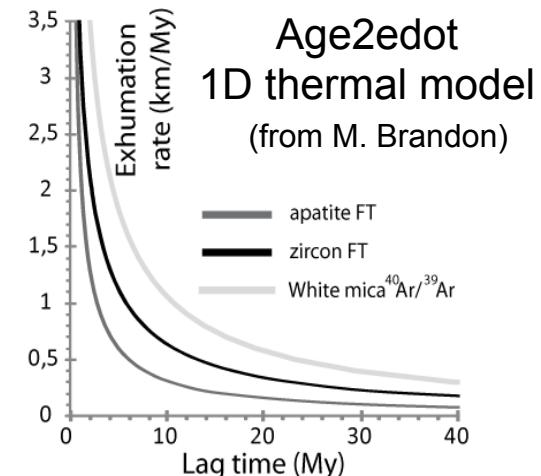

- Granodiorite signal : U/Pb age of about 290 Ma
- Alpine ZFT signal is less developed than in the pro-side foreland basin deposits
- No Oligocene volcanic zircons

Pro-side foreland P1 zircon fission-track signal

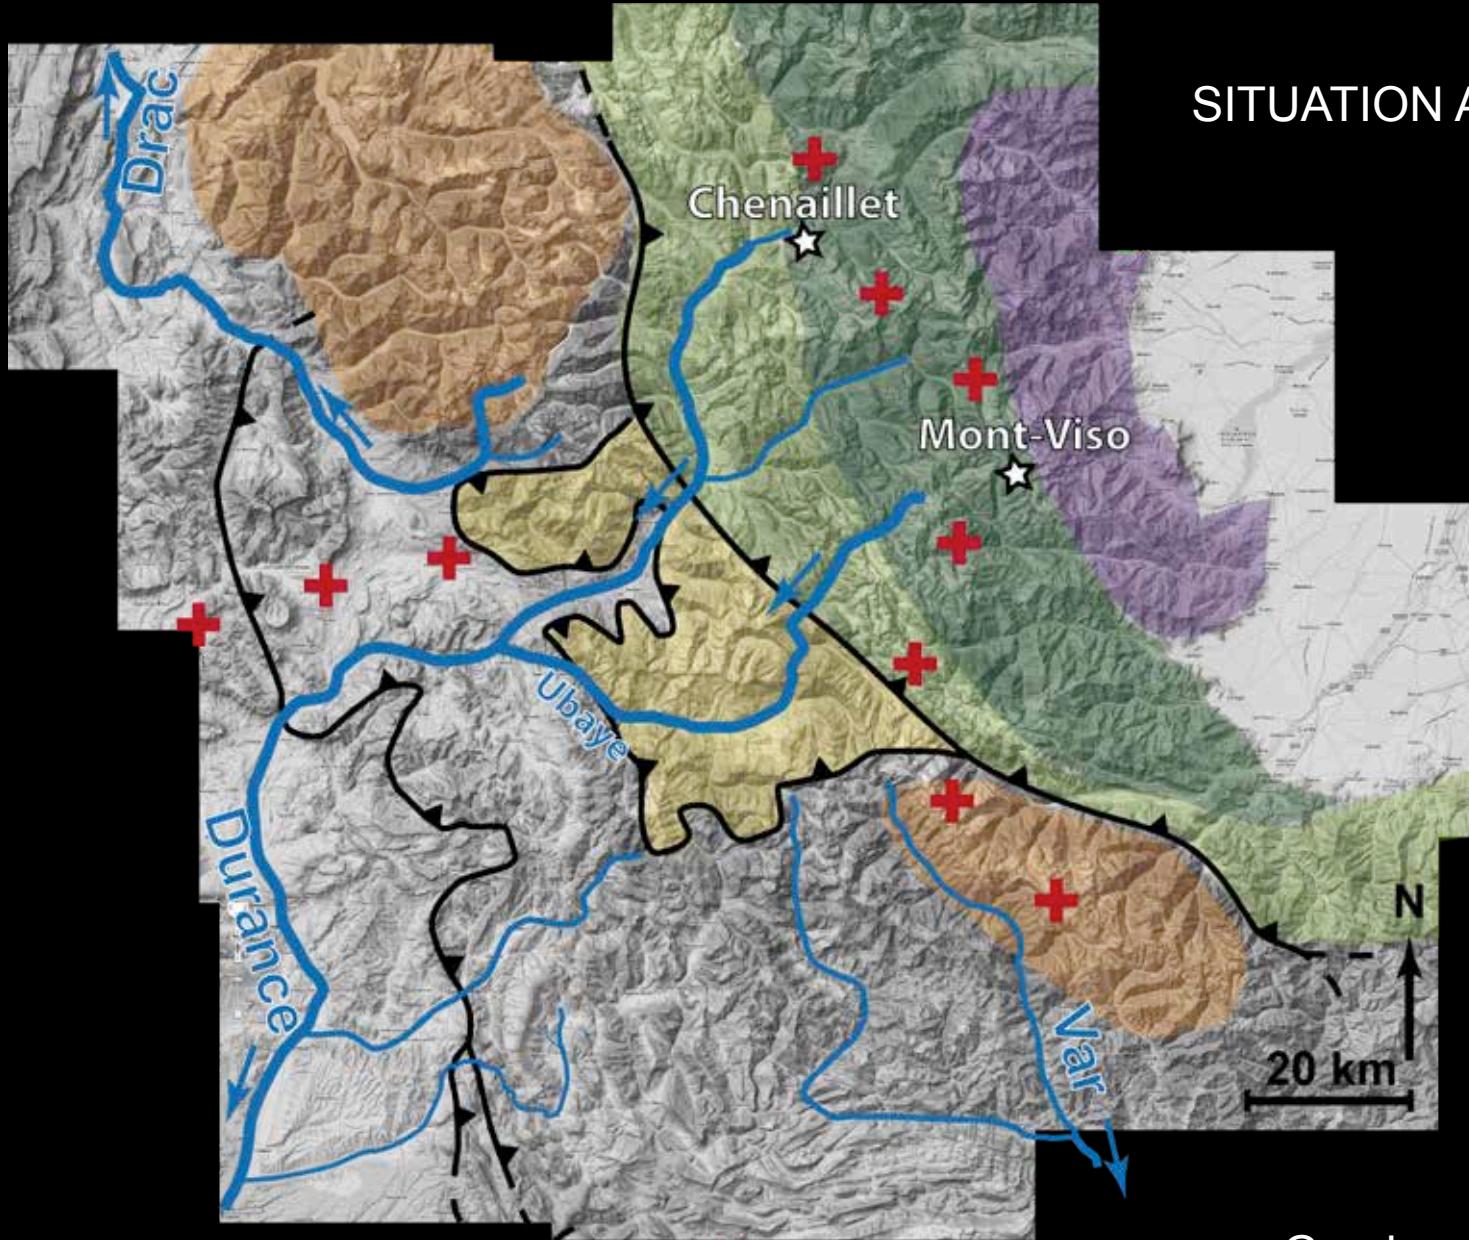

Age - exhumation rate relationship from modelization

Age2edot
1D thermal model
(from M. Brandon)

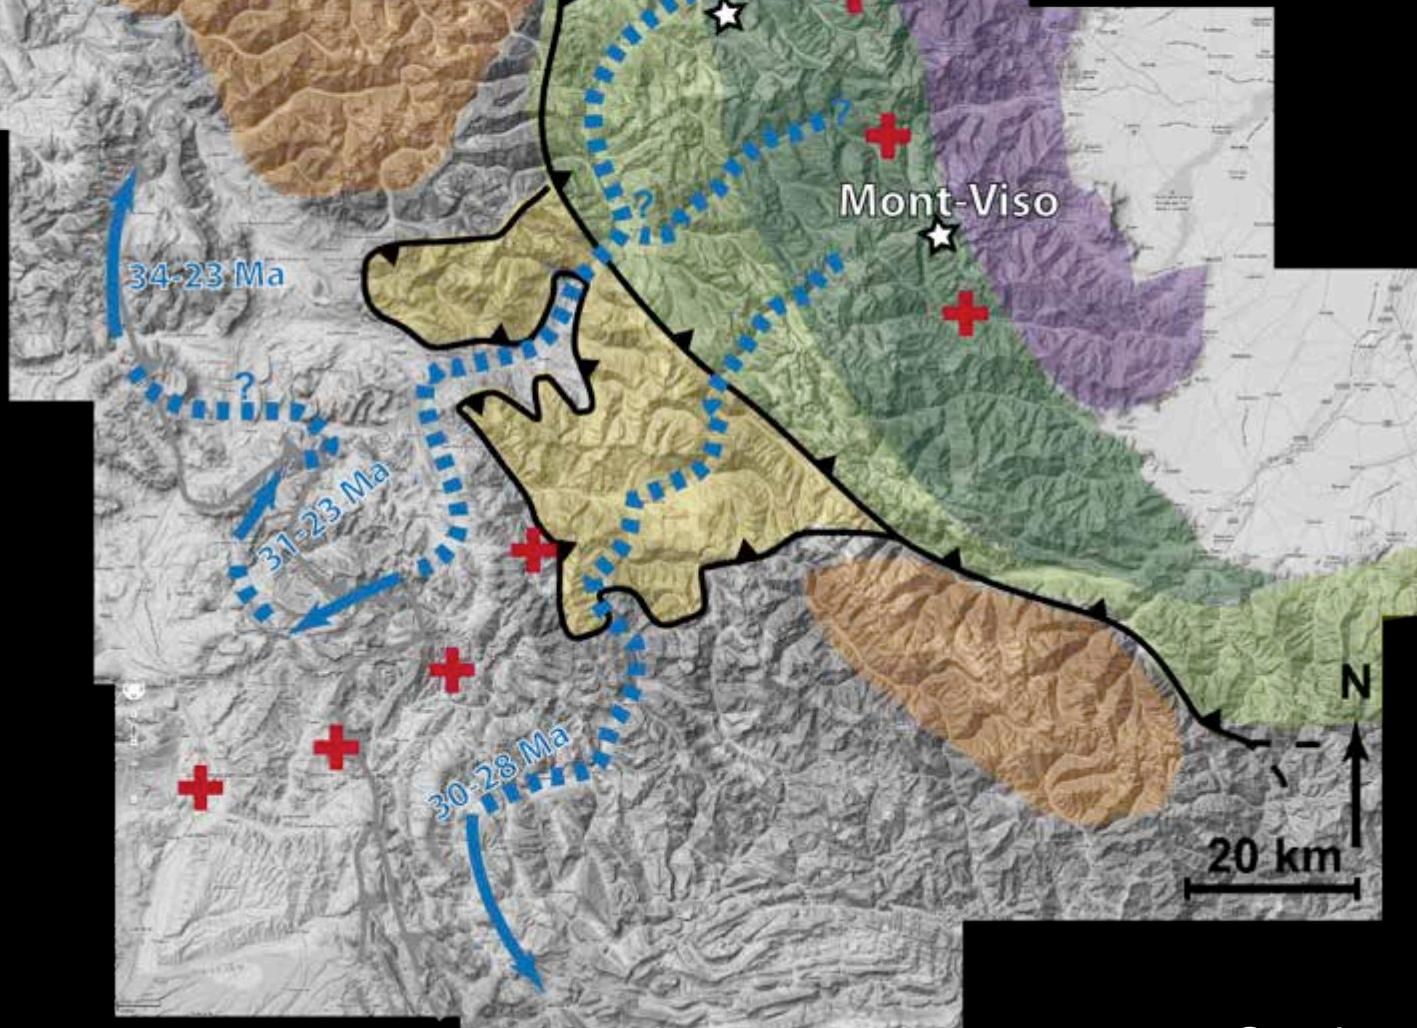

- Brief period of fast exhumation at \sim 1.5 to 2 km/Myr
- Arrival of pebbles from Internal Alps is contemporaneous with this brief pulse of rapid erosional exhumation

SITUATION ACTUELLE

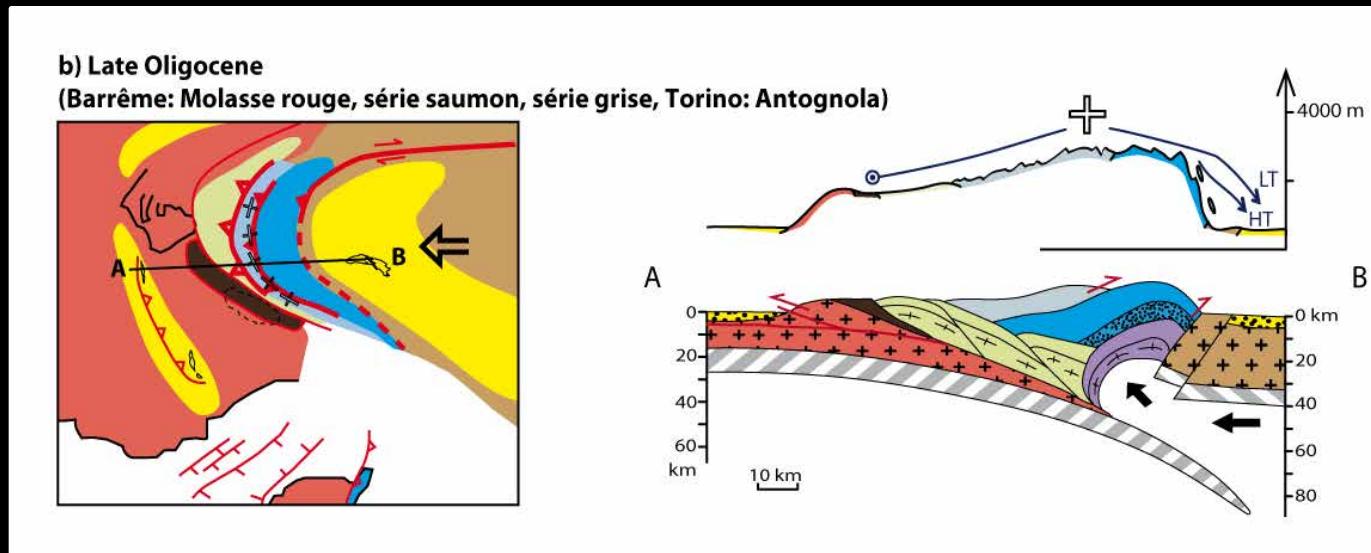

Grosjean, 2012

DRAINAGE OLIGOCENE

Grosjean, 2012

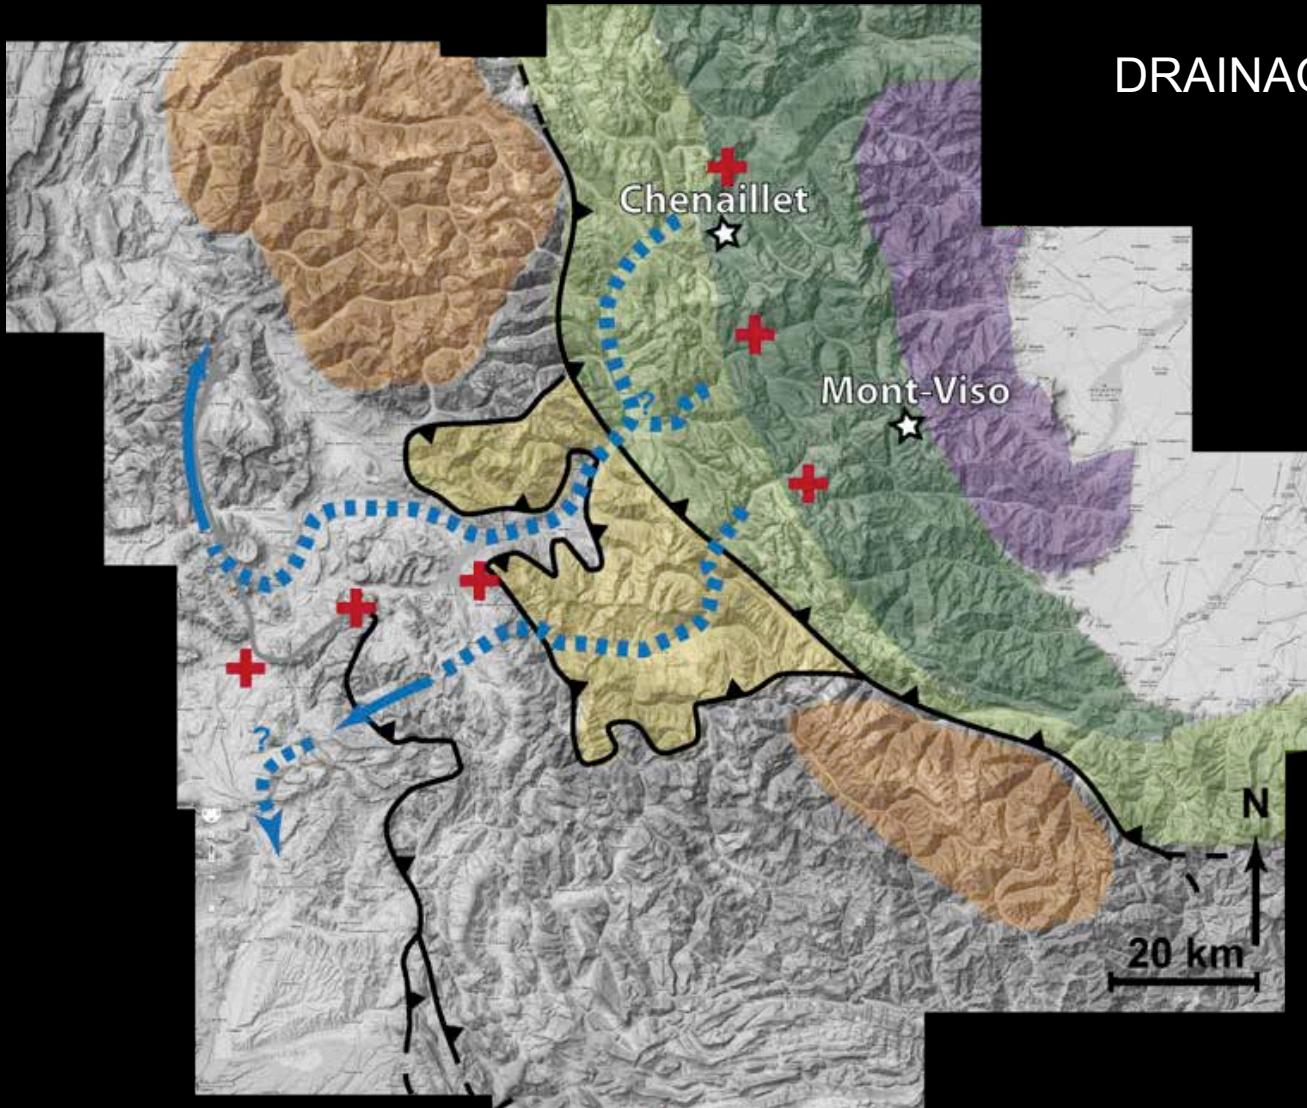

Drainage divide evolution

Exhumation rate 1.5 to 2 km/Myr

Jourdan et al Journal of Geology , 2012

- Pebble lithologies in foreland basins on both sides of the Alps allow tracing the drainage divide evolution
- Large pebbles in the Torino hills show the proximity of steep relief

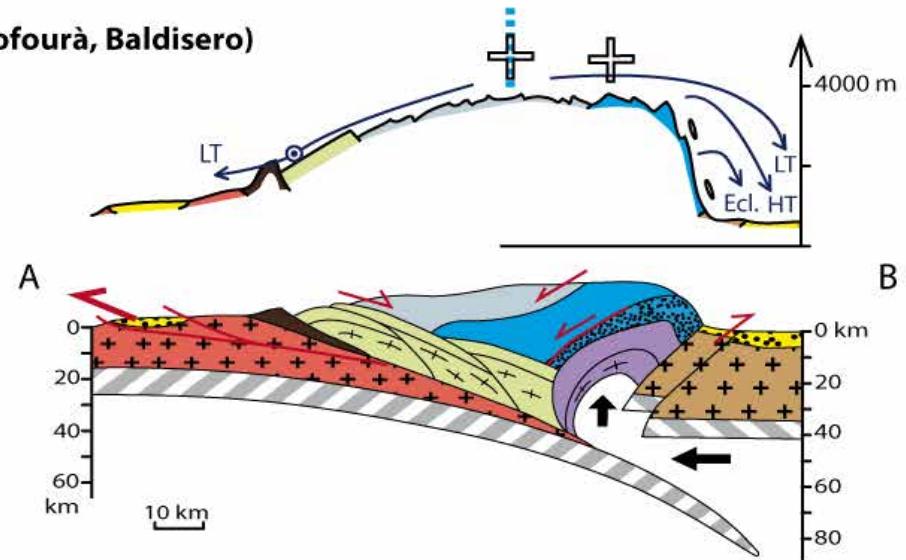

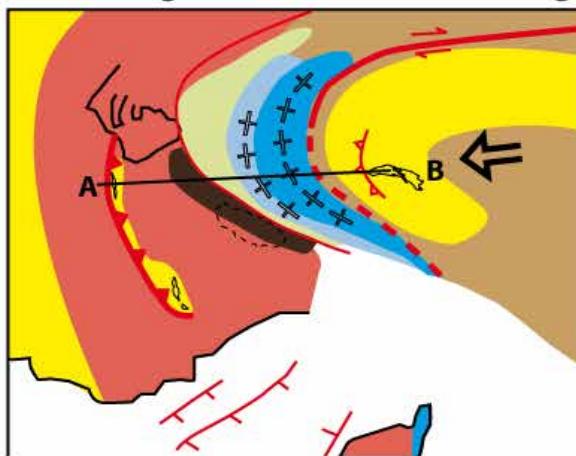

DRAINAGE MIOCENE

Grosjean, 2012

Drainage divide evolution

c) Lower Miocene

(Barrême: grès vert, Torino: late Antognola, Termofourà, Baldisero)

Exhumation rate 0.4 km/Myr

Jourdan et al Journal of Geology , 2012

- Pebble lithologies in foreland basins on both sides of the Alps allow tracing the drainage divide evolution
- Large pebbles in the Torino hills show the proximity of steep relief

Conclusion : Reliefs des Alpes

Les reliefs récents à actuels (< 5 Ma) sont formés par incision glaciaire

Les reliefs dans les Alpes existent depuis environ 30 Ma
(probablement plus mous qu'actuellement)

Les altitudes > 3000 mètres existent depuis 30 Ma

Les altitudes > 4000 mètres plus récentes (< 5 Ma)

La ligne de partage des eaux à peu changée
